Pattison, Harry Archibald, Claverack, N Y, born in 1877, Chicago Homeopathic Medical College, 1904, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910, fellow of the American College of Physicians, member of the American Trudeau Society, British Tuberculosis Association, and the International Union Against Tuberculosis, served as supervisor of the medical service of the National Tuberculosis Association, formerly director of the Potts Memorial Institute in Livingston, author of 'Rehabilitation of the Tuberculous', died in the Columbia Memorial Hospital, Hudson, Feb 14, aged 79, of cerebral hemorrhage

Reisinger, John Charles ⊕ Washington, D C, born in Rockville, Md, Aug 23, 1901, George Washington University School of Medicine, Washington, D C, 1927, specialist certified by the American Board of Internal Medicine, medical adviser to the district branch of the Selective Service System, instructor of medicine at Johns Hopkins University School of Medicine, Baltimore, from 1930 to 1931, when he became clinical instructor of medicine at George Washington University School of Medicine, serving until 1935, formerly on the staff of the Central Dispensary and Emergency Hospital, died in the George Washington Hospital March 5, aged 55

Wiedenmann, John Charles ⊕ Englewood, Colo, born in Hepler, Kan, June 14, 1899, Johns Hopkins University School of Medicine, Baltimore, 1930, served as secretary and president of the Arapahoe County Medical Society, for many years county health officer and city physician, one of the founders and past-president of the Englewood Rotary Club, a director of the Denver Chapter of Arthritis and Rheumatism Foundation, served on the staffs of Swedish National Sanatorium in Englewood, and St Luke's Hospital and the Porter Sanitarium and Hospital in Denver, where he died Jan 12, aged 57, of cerebral hemorrhage

Eisenstein, Victor William ⊕ New York City, born Sept 15 1904, George Washington University School of Medicine, Washington, D C, 1929, specialist certified by the American Board of Psychiatry and Neurology, member of the American Psychosomatic Society, fellow of the American Psychiatric Association, served a residency at the New York State Psychiatric Institute and Hospital in New York City, chief in psychiatry at the Lenox Hill Hospital, editor of 'Neurotic Interaction in Marriage and the author of articles in the scientific journals, died Feb 3, aged 52, of coronary disease

Foley, Floyd K ⊕ Owensboro, Ky, born March 29, 1885, University of Louisville (Ky) Medical Department, 1911, specialist certified by the American Board of Psychiatry and Neurology, member of the American Psychiatric Association, past-president of the Kentucky Psychiatric Association, veteran of World War I, formerly superintendent of the Eastern State Hospital in Lexington and the Western State Hospital in Hopkinsville, at one time with the Pension Bureau in Washington, D C, died in the Veterans Administration Hospital, Louisville, Feb 3, aged 71, of myocardial infarction

Mecray, Paul Mulford, Camden, N J, University of Pennsylvania Department of Medicine, Philadelphia, 1892, member of the founders group of the American Board of Surgery, veteran of the Spanish-American War, for many years secretary of the Camden County Medical Society, fellow of the American College of Surgeons, retired chief of staff, Cooper Hospital, where he was a member of the board of managers, served on the staff of the Salem (N J) County Memorial Hospital and the Zurbrugg Memorial Hospital, Riverside, died in Lake Wales, Fla, Feb 13, aged 85, of coronary occlusion

Joelson, James Joel ⊕ Cleveland, Columbia University College of Physicians and Surgeons, New York City, 1920, clinical professor of urology at the Western Reserve University School of Medicine, specialist certified by the American Board of Urology, member of the American Urological Association, fellow of the American College of Surgeons, veteran of World War II, associate surgeon in charge of genitourinary surgery, University Hospitals of Cleveland, died in the Hanna House of University Hospitals Feb 8, aged 59, of coronary thrombosis

Howe, Hubert Shattuck ⊕ New York City, Columbia University College of Physicians and Surgeons, New York City, 1912, specialist certified by the American Board of Psychiatry and Neurology, member of the American Neurological Association and the Association for Research in Nervous and Mental Diseases, for many years clinical professor of neurology at his alma mater, served on the staffs of the Presbyterian Hospital and the Neurological Institute, died in the Roosevelt Hospital Feb 4, aged 68

Maresh, Henry Rudolph ⊕ Houston, Texas, University of Texas School of Medicine, Galveston, 1919, formerly clinical assistant professor of clinical medicine at the Baylor University College of Medicine, member of the staffs of St Joseph's and Methodist hospitals, on the visiting staff of Hermann Hospital, a consultant in internal medicine at Polly Ryon Memorial Hospital, Richmond, died in the M D Anderson Hospital Jan 28, aged 66, of bronchogenic carcinoma with metastases

Aday, J Leo ⊕ Little Rock, Ark, University of Arkansas School of Medicine, Little Rock, 1937, fellow of the American College of Surgeons, veteran of World War II, on the staffs of the St Vincent Infirmary and the Arkansas Baptist Hospital, where he died Feb 15, aged 44, of coronary thrombosis

Becker, William Christian, Winter Park, Fla, Jefferson Medical College of Philadelphia, 1917, service member of the American Medical Association, at one time an officer in the regular Navy, retired from the Veterans Administration on March 28, 1956, died Feb 19, aged 67

Comer, Robert T ⊕ Birmingham, Ala, Johns Hopkins University School of Medicine, Baltimore, 1901, for many years head of the health department of the Avondale Mills, died March 4, aged 80, of ascending kidney infection and benign prostatic obstruction

Dozier, William Bate ⊕ Nashville, Tenn, University of Nashville Medical Department, 1905, member of the American Academy of General Practice, died in the Mid-State Baptist Hospital Jan 27, aged 74, of pneumonia

Eichenbronner, David, Amsterdam, N Y, Albert-Ludwigs-Universitat Medizinische Fakultat, Freiburg, Baden, Germany, 1902, an associate member of the American Medical Association, on the staffs of the Amsterdam City Hospital and St Mary's Hospital, where he died Jan 25, aged 78, of arteriosclerotic coronary artery disease

Ernst, Harold Oliver, New Orleans, Tulane University School of Medicine, New Orleans, 1922, member of the Louisiana State Medical Society, died in the Touro Infirmary Nov 26, aged 57, of bronchogenic carcinoma of the right lung

Farquhar, Elwood Miller, Santa Monica, Calif, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1897, died Jan 17, aged 88

Fisher, Leon Gabriel, New York City, Columbia University College of Physicians and Surgeons, New York City, 1912, medical examiner for the New York State Department of Labor, died in the Maimonides Hospital, Brooklyn, Feb 3, aged 66, of ruptured aortic aneurysm

Forbes, Stephen Alfred ⊕ Chicago, Rush Medical College, Chicago, 1937, assistant professor of radiology at the University of Illinois College of Medicine, at one time assistant professor of radiology at the State University of Iowa College of Medicine in Iowa City, specialist certified by the American Board of Radiology, member of the Radiological Society of North America and the American College of Radiology, died March 16, aged 47

Fuesy, Joseph Ralph, Croton-on-Hudson, N Y, New York Medical College, Flower and Fifth Avenue Hospitals, New York City, 1953, interned at Grasslands Hospital in Valhalla, certified by the National Board of Medical Examiners, served a residency at the White Plains (N Y) Hospital and St Luke's Hospital in New York City, where he died Jan 31, aged 32, of leukemia

Garding, Clarence Jacob, Jefferson, Wis, Creighton University School of Medicine, Omaha, 1927, veteran of World War I, on the staffs of the Fort Atkinson (Wis) Memorial Hospital and the St Mary's Hospital in Watertown, where he died Jan 25, aged 57, of polycystic kidney

Gerwitz, Bernard William ⊕ St Louis, St Louis University School of Medicine, 1930, instructor in gynecology and obstetrics at his alma mater, member of St Louis Medical Society and St Louis Gynecological Society, since 1933 assistant gynecologist and obstetrician at St Mary's Group of Hospitals, formerly on the staff of St Louis City Hospital, died Jan 29, aged 53, of cancer

Gilstrap, William J, ⊕ Portland, Ore, College of Physicians and Surgeons of San Francisco, 1903, died in the Grande Ronde Hospital, La Grande, Feb 12, aged 86, of carcinoma of the colon with metastases

Givens, Robert T, New Castle, Va, University College of Medicine, Richmond, 1901, died in the Lewis Gale Hospital, Roanoke, Dec 23, aged 80

Goldstein, David, Brooklyn, Long Island College Hospital, Brooklyn, 1906, died Jan 3, aged 72, of arteriosclerotic heart disease

Graves, Allen Bouthrod, New York City, Howard University College of Medicine, Washington, D C, 1908, died Feb 3, aged 78, of cerebral arteriosclerosis

Greenberg, Samuel ⊕ Newark, N J, University and Bellevue Hospital Medical College, New York City, 1904, on the staff of the Beth Israel Hospital, where he died Feb 8, aged 75, of cerebral hemorrhage

Gregory, Dewey Quintin ⊕ Eureka, Calif, College of Medical Evangelists, Loma Linda and Los Angeles, 1943, interned at the Los Angeles County Hospital, in Los Angeles, killed in an automobile accident Feb 3, aged 58

Gruskin, Harry ⊕ Brooklyn, Boston University School of Medicine, 1928, veteran of World War II, died in the Mount Sinai Hospital, New York City, Jan 14, aged 52, of diabetes mellitus, cirrhosis of the liver, and nephrosis

Guy, Franklin Wheeler, New Castle, Pa, Western Pennsylvania Medical College, Pittsburgh, 1906, an associate member of the American Medical Association, on the staff of the Jameson Memorial Hospital, died Feb 6, aged 86, of cerebral hemorrhage

Hall, Samuel J, ⊕ Medical Director, U S Public Health Service, Philadelphia, University of Louisville (Ky) School of Medicine, 1927, died Feb 1, aged 57, of coronary occlusion

Hamilton, Robert Lucian ⊕ Marysville, Calif, University of Tennessee College of Medicine, Memphis, 1929, member of the American Academy of General Practice, fellow of the International College of Surgeons, veteran of World War II, decorated with the Purple Heart and received the Army Commendation Ribbon, past-president of the Yuba-Sutter-Colusa Counties Medical Society, died Feb 1, aged 52, of coronary occlusion

Haney, Frederick Charles ⊕ Watertown, Wis, Bennett College of Eclectic Medicine and Surgery, Chicago, 1907, died in St Mary's Hospital Dec 9, aged 77, of lymphosarcoma and pneumonia

Harris, Carl Nathaniel ⊕ Hibbing, Minn, Rush Medical College, Chicago, 1915, past-president of the Minnesota State Sanitary Association, veteran of World War I, village health officer from 1934 to 1942, on the staff of the Adams Clinic and Hibbing General Hospital, died in the Methodist Hospital, Rochester, Minn, Feb 10, aged 69, of carcinoma of the lung

Hayes, Floyd Warner ⊕ Bradford, Pa, University of Buffalo School of Medicine, 1914, specialist certified by the American Board of Otolaryngology, fellow of the American College of Surgeons, veteran of World War I, an honorary member of the staff of the Bradford Hospital, where he died Feb 9, aged 67, of cerebral hemorrhage

Heath, Guy Wilkerson, West Palm Beach, Fla, Tulane University School of Medicine, New Orleans, 1920, member of the Florida Medical Association, member of the staff of St Mary's Hospital, where he was on the advisory board, and the Good Samaritan Hospital, died in Jupiter Feb 3, aged 62, as the result of a boat accident while fishing in the ocean

Heberding, John ⊕ Youngstown, Ohio, Western Pennsylvania Medical College, Pittsburgh, 1905, specialist certified by the American Board of Radiology, member of the American Roentgen Ray Society and the American College of Radiology, on the staff of the Youngstown Hospital, died Jan 26, aged 74, of cancer

Hildebrant, Paul Wiley, Mount Sterling, Ohio, University of Michigan Homeopathic Medical School, Ann Arbor, 1912, formerly mayor, died in Washington C H, Jan 30, aged 80

Hollings, Byam ⊕ Concord, N H, Harvard Medical School, Boston, 1906, in 1914 member of the House of Delegates of the American Medical Association, member of the Massachusetts Medical Society, veteran of World War I, retired assistant medical director for the John Hancock Life Insurance Company in Boston, died Jan 25, aged 79, of cerebral vascular accident

Hopkins, Howard Leslie ⊕ Leavenworth, Wash, University of Nebraska College of Medicine, Omaha, 1928, veteran of World War II, died Feb 17, aged 55

Horwitz, John B ⊕ Detroit, Detroit College of Medicine and Surgery, 1926, veteran of World War II, member of the American Academy of General Practice, on the staffs of Grace and Sinai hospitals, died Jan 13, aged 55, of coronary occlusion

Hughes, Fred Morris ⊕ Houston, Texas, University of Texas School of Medicine, Galveston, 1926, veteran of World War I and II, at one time associate professor of clinical surgery at Baylor University College of Medicine, on the staffs of the Memorial, Hermann, and St Luke's hospitals, on the courtesy staff of St Joseph s Hospital, where he died Jan 28, aged 58, in the operating room after completing a minor operation on a patient

Hull, Austin Oliver ⊕ San Antonio, Texas, University of Louisville (Ky) Medical Department, 1913, for many years city bacteriologist, died in Santa Rosa Hospital Jan 28, aged 65, of thrombosis

Hunter, John Russell Wightman, Lewistown, Pa, Medico-Chirurgical College of Philadelphia, 1893, an associate member of the American Medical Association, fellow of the American College of Surgeons, member of the surgical staff and board of trustees for many years at the Lewistown Hospital, where he died Jan 26, aged 88, of cerebral thrombosis

Hutchinson, Sankey Smith, Bladenboro, N C, North Carolina Medical College, Charlotte, 1911, member of the Medical Society of the State of North Carolina, served as past-president of the Bladen County Medical Society, chairman of the city and county board of education, surgeon for the Scotland Air Line Railway, on the staff of the Robeson County Memorial Hospital, Lumberton, where he died Feb 11, aged 68, of myocardial infarction

Jacobs, William Rigby ⊕ Lewiston, Idaho, Rush Medical College, Chicago, 1937, specialist certified by the American Board of Ophthalmology, veteran of World War II, receiving the Air Medal with three oak leaf clusters, chairman of the ophthalmological section, St Joseph's Hospital, died Jan 26, aged 50, probably of coronary thrombosis

Jamieson, William Ross ⊕ El Paso, Texas, McGill University Faculty of Medicine, Montreal, Quebec, Canada, 1898, also a graduate in pharmacy, past president of the El Paso County Medical Society, veteran of World War I, on the staff of the El Paso General Hospital and the Hotel Dieu, Sisters' Hospital, died in the Veterans Administration Hospital, Fort Bayard, N Mex, Jan 24, aged 81

Jamison, Euell Claude ⊕ Rocky Mount, Va, Medical College of Virginia, Richmond, 1927, veteran of World War II, member of the Roanoke Academy of Medicine, member of the Rocky Mount Town Council, a director of the Bankers Trust Company of Rocky Mount, trustee of the Franklin Memorial Hospital, where he was an active member of the medical staff, died Jan 29, aged 56, of lymphosarcoma

Johnston, Irwin, Cohoes, N Y, Albany (N Y) Medical College, 1911, an associate member of the American Medical Association, served on the staff of the Samaritan Hospital in Troy, died Feb 13, aged 70, of arteriosclerotic heart disease

Jones, J N, Bastrop, La, Memphis (Tenn) Hospital Medical College, 1907, member of the Louisiana State Medical Society died in the Bastrop General Hospital Nov 29, aged 76, of congestive heart disease

Kazlauckas, Anthony John ⊕ Cleveland, St Louis University School of Medicine, 1931, formerly Cuyahoga County deputy coroner, on the staff of the Polyclinic Hospital, where he died Jan 18, aged 52, of cerebral hemorrhage

Landis, James Calvin, Pennsburg, Pa, Medico Chirurgical College of Philadelphia, 1902, for many years member of the school board, served on the staff of the Quakertown (Pa) Community Hospital, where he died Feb 10, aged 79

Lanning, Walter Benjamin, De Queen, Ark, University of Arkansas School of Medicine, Little Rock, 1913, died Feb 7, aged 72, of aneurysm of the aorta

Latta, Reginald Heber, Graysville, Ohio, Ohio State University College of Medicine, Columbus, 1917, member of the Ohio State Medical Association, mayor of Graysville and president of the Monroe County Board of Health, died Jan 18, aged 64, of coronary thrombosis

Lauter, Leo ⊕ Toledo, Ohio; Albertus-Universitat Medizinische Fakultat, Konigsberg, Prussia, Germany, 1920; member of the American Academy of General Practice; on the staffs of the St. Luke's and Flower hospitals; died Feb. 11, aged 63.

Leaper, Warren Eugene ⊕ Green Bay, Wis.; Johns Hopkins University School of Medicine, Baltimore, 1911; past-president of the Brown-Door-Kewaunee Counties Medical Society; on the staffs of St. Vincent's, Bellin Memorial, and St. Mary's hospitals; died Jan. 20, aged 70, of coronary occlusion.

Leavitt, Thomas William, Malden, Mass.; College of Physicians and Surgeons, Boston, 1920; member of the Massachusetts Medical Society; veteran of World War I; formerly Malden alderman; died in Medford Feb. 6, aged 65.

Lemon, Charles Warner, Lewisburg, W. Va.; University College of Medicine, Richmond, 1898; an associate member of the American Medical Association; in 1914-1915 member of the state legislature; staff physician at Greenbrier Military School from 1932 until 1955; died in the Greenbrier Valley Hospital, Ronceverte, March 6, aged 81.

Leonard, John Vaughn, Menlo Park, Calif.; Medical Department of the University of California, San Francisco, 1901; died in the Palo Alto (Calif.) Hospital Jan. 28, aged 79.

Lessig, James Blee ⊕ Sinking Spring, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1930; on the staff of the Reading (Pa.) Hospital, where he died Jan. 23, aged 51, of carcinoma of the lung.

MacFarlane, Nowland, Pacific Palisades, Calif.; Beaumont Hospital Medical College, St. Louis, 1900; formerly practiced in Los Angeles, where he was on the staffs of the Clara Barton, Queen of Angels, and Methodist hospitals; died Jan. 26, aged 80.

McEwan, James William, Alma, Mich.; L.R.C.P., Edinburgh and L.R.C.S., Edinburgh, Scotland, 1904; Detroit College of Medicine, 1907; veteran of the Spanish-American War and World War I; formerly practiced in Detroit, where he was on the staff of the Harper Hospital; died Jan. 23, aged 80, of carcinoma of the rectum.

McLean, Harold Guy ⊕ Detroit; Detroit College of Medicine and Surgery, 1920; fellow of the International College of Surgeons and the American College of Surgeons; vice-chief of surgery at the Grace Hospital, where he died Feb. 8, aged 60, of coronary occlusion.

McWilliams, Jacob Marvin ⊕ Fayetteville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1901; died in the Lincoln County Hospital Feb. 2, aged 79, of cerebral hemorrhage.

Mars, John Francis, Newburgh, N. Y.; McGill University Faculty of Medicine, Montreal, Quebec, Canada, 1918; member of the Medical Society of the State of New York; served on the staff of the Cornwall (N. Y.) Hospital, on the courtesy staffs of Goshen (N. Y.) Hospital and St. Luke's Hospital; died Jan. 26, aged 64.

Max, Clarence Oscar Christian ⊕ St. Louis; Washington University School of Medicine, St. Louis, 1899; served on the staffs of St. Mary's Hospital, St. Mary's Infirmary, St. Anthony Hospital and Missouri Baptist Hospital; died in Barnes Hospital Feb. 15, aged 82, of myocardial infarction.

Mayo, Bessie Evelyn, Oklahoma City, Okla.; Baylor University College of Medicine, Dallas, Texas, 1923; died Jan. 20, aged 58, of rheumatic heart disease.

Mellies, George Augustus ⊕ St. Louis; Homeopathic Medical College of Missouri, St. Louis, 1895; member of the American Academy of General Practice; veteran of World War I; for many years associated with the Christian Hospital, where he was for many years chief surgeon and president of the medical staff and where he died Feb. 1, aged 82, of heart disease.

Mellman, Clarence, Los Angeles; College of Physicians and Surgeons, Los Angeles, 1917; died Jan. 29, aged 62, of acute cardiac failure.

Messerly, Charles Buchanan ⊕ Martins Ferry, Ohio; College of Physicians and Surgeons, Baltimore, 1902; for many years served on the board of education of Martins Ferry; at one time county coroner; veteran of World War I; a director of the Citizens Savings Bank; one of the founders of the Martins Ferry Hospital, where he was a member of the staff, and where he died Jan. 31, aged 77, of coronary disease.

Moore, Russell Malachi ⊕ Atlanta, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1885; died Jan. 21, aged 93, of carcinoma of the lungs.

Morris, Harry Rembert ⊕ Birmingham, Ala.; University of Nashville (Tenn.) Medical Department, 1906; died in Miami, Fla., Feb. 13, aged 73, of pulmonary edema, portal cirrhosis, and portal-vein thrombosis.

Murray, Robert Allen ⊕ La Mesa, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1938; certified by the National Board of Medical Examiners; served on the staffs of Mercy and Quintard hospitals in San Diego; died Jan. 17, aged 47, of squamous-cell carcinoma of the tongue and floor of mouth.

Myers, Lloyd ⊕ San Diego, Calif.; University of Nebraska College of Medicine, Omaha, 1918; died Dec. 21, aged 65, of hypertensive cardiovascular heart disease.

Owen, John Atkinson, South Boston, Va.; University of Virginia Department of Medicine, Charlottesville, 1903; died in the Veterans Administration Hospital, Richmond, Jan. 24, aged 76, of arteriosclerosis.

Pantera, George Benedict ⊕ Buffalo; Georgetown University School of Medicine, Washington, D. C., 1936; certified by the National Board of Medical Examiners; formerly practiced in Oak Hill, where he was on the staff of the Oak Hill Hospital; died in Cleveland Feb. 8, aged 47, of heart disease.

Parmenter, Bert Newton, Sheboygan, Wis.; Northwestern University Medical School, Chicago, 1896; died in the Sheboygan Memorial Hospital Feb. 26, aged 86, of auricular fibrillation, and coronary sclerosis.

FOREIGN LETTERS

INDIA

Basal Cell Carcinoma —M V Sirsat (*Indian J M Sc* 11 1, 1957) compared the age, incidence, site of occurrence, and histopathology of basal cell carcinoma in Indians and Europeans Between 1941 and 1955, 200 cases of basal cell carcinoma were recorded in the laboratories of the Tata Memorial Hospital, Bombay, of which 148 occurred in Indians and 52 in Europeans Most of these patients were between 41 and 60 years of age There was no significant difference in age distribution in the two groups The most frequent sites of occurrence of the tumor in Indians were the cheek, eyelids, and nose, while in Europeans the most frequent site was the nose The reticulated variety of basal cell carcinoma was commonest in Europeans and the adenoid cystic type in Indians

Shortage of Nurses —At the meeting of the Central Council of Health at Ranchi, there was deep concern over the limited progress made in implementing the recommendations of the nursing committee Therefore, the council again urged state governments to improve the emoluments and working conditions of nurses About 17 000 nurses and 21,000 midwives are practicing in India This number falls far short of the needs The health survey and development committee had recommended that there should be a ratio of one nurse to every 500 persons and one midwife for every 100 births On this basis, the total requirements of nurses and midwives would be 70,000 and 87,500 respectively In order to meet the increasing demand for health personnel, a plan for training about 6,000 additional auxiliary-nurse midwives has been included in the second Five-Year Plan

Lymphomas of the Pharynx —G V Talwalkar (*J Postgraduate Med* 3 1, 1957) studied 54 cases of malignant lymphoma of the pharynx, which constituted 10% of the proved malignant lymphomas encountered in a period of 15 years The patients varied in age from 6 to 85 years, 35 being between 30 and 60 The duration of symptoms varied from eight days to one year, the most usual time being two to three months Swelling of the neck was the main complaint in 20 cases Generalized enlargement of lymph nodes was present in three patients Pain in the throat was a common complaint Difficulty in swallowing was present in 13 patients, a mass in the throat in 11, a change in voice in 5, and epistaxis in 4 Deafness was the only complaint in one The tonsils were primarily involved in 35 patients Of these, 10 showed an ulcerative lesion, 5 showed a bulky growth, 6 showed uniform enlargement of the tonsils, and 9 had a nodular growth Most nasopharyngeal lymphomas were large and occupied most of the nasopharyngeal space Lesions seen at the base of the tongue were either ulcerative or nodular Lymph nodes were palpable in 45 cases Most of the patients underwent irradiation therapy, three after tonsillectomy Complete regression of the primary lesion and the cervical lymph nodes was seen within two months in 24 patients Partial response was noticed in 12 One patient with generalized lymphosarcoma with a lesion in the tonsil responded well to nitrogen mustard A complete follow-up was not available, as patients failed to return Histologically, follicular lymphoma was diagnosed in two patients, both in the tonsils

Nystatin in the Treatment of Moniliasis —Pohowalla and co-workers (*Indian J M Sc* 11 1, 1957) stated that, since thrush is commonly seen in children, they sought to assess the effectiveness of nystatin in its treatment Twenty-eight children with thrush were studied clinically and 27 of these also bacteriologically The disease was clinically cured in 75% of the patients by the seventh day of treatment Cultures became negative in 60% of the children within the same period The nystatin was given orally Diarrhea was the commonest complication of thrush, being present in 75% of the patients, 13 of these patients also showed dehydration All the seven deaths that occurred in the series were in dehydrated patients

Isolated Fracture of the First Rib —Donaldson and Marshall (*Indian Journal of Surgery*, December, 1956) reported a case of isolated fracture of the first rib This condition is so infrequently encountered that it is apt to be missed This is due to the situation of the first rib deep in the base of the neck, where it is usually protected from trauma by the shoulder girdle The importance of this fracture lies in the fact that it may result in rupture of the apex of the lung, abscess formation, pleurisy with effusion hemorrhage, nerve pressure and Horner's syndrome The authors' patient was a 54-year-old man who, while lifting baggage, had felt a sudden excruciating pain in the left upper portion of his chest This was followed by breathlessness and faintness These symptoms were relieved by nikethamide and coffee The pain persisted but was ignored by the patient till about six weeks later when he started getting pain in the left side of his neck, left shoulder, and arm The pain increased in severity and radiated down to the tips of his middle and ring fingers He also complained of a feeling of something filling the left upper portion of his chest A roentgenogram showed fracture of the left first rib at the costochondral junction

NEW ZEALAND

Synaptic Transmission in Sympathetic Ganglions —At the 32nd meeting of the Australian and New Zealand Association for the Advancement of Science, in Dunedin, in January, Rosamond M Eccles of the Australian National University, Canberra, reported that when the synaptic transmission of impulses through the isolated superior cervical ganglion was blocked by

---

The items in these letters are contributed by regular correspondents in the various foreign countries

curare-like substances, preganglionic impulses still produced three types of postganglionic potentials a synaptic potential, a later positive potential (P wave), and a late negativity (LN) wave superimposed on the latter part of the P wave Addition of any anticholinesterase, in a suitable concentration, causes a complete disappearance of the LN wave, and thereby reveals the full size and time course of the P wave This effect of anticholinesterases is due to their anticholinesterase action and not to any depolarization of the postsynaptic membrane, since depolarizing agents such as nicotine or increased potassium ion concentration do not selectively decrease the LN wave Other pharmacological agents such as epinephrine, strychnine, and veratrine do not cause any appreciable alteration in the size or time courses of the synaptic potentials, the positivity wave, or the late negativity wave Such results indicate that synaptic transmission in the sympathetic ganglion is more complicated than at the neuromuscular junction, where only a single transmitter appears to be operating on a single type of membrane receptor

Bloat —Bloat is a disorder of ruminants that occurs wherever grazing of legumes is practiced It is the result of interference with elimination of gas that is normally produced by the bacterial fermentation of food in the rumen and reticulum At the same meeting, A T Johns and co-workers of Palmerston North reported the results of trials undertaken to test the various theories put forward to explain the cause of the ailment It was found that most of the gas produced was being retained in a foam and therefore not free to be eructated A system of control of bloat caused by leguminous pastures was evolved, using vegetable oils as antifoaming agents The tendency of certain animals to bloat appears to be an inherited characteristic, and, hence, both pasture and animal factors seem to be involved Trials with the use of orally administered penicillin to protect animals from bloat indicate that the flora of the rumen is a major contributing factor

Endocrine Adaptations to the Tropics —At the same meeting Prof W V Macfarlane of Brisbane stated that metabolic rate and thyroid activity have been found to be depressed in rats, sheep, and man by periods of living at temperatures above 30 C Food intake is reduced and water intake increased The metabolically active components of the adrenal steroid secretion also appear to be depressed during the hot seasons and elevated during the cooler parts of the year This applies to 17-ketosteroid output and 17-hydroxycorticoid excretion The intake of water by man and sheep in summer is increased to about 12 times the winter intake When evaporative cooling is employed in the hotter parts of the year, antidiuretic hormone appears in the blood to reduce urine flow Urine flow, however, is reduced at these times without there being measurable amounts of antidiuretic hormone in the blood The antidiuretic hormone appears to be an adjuvant to other water-saving mechanisms It is released by heat (four hours at 41 C) in summer, but not in winter, in man and sheep

In both species, the ratio of potassium to sodium in the urine is high in summer and low in winter This is associated with aldosterone excretion after sweat-producing exercise such as that described by Neher and Wettstein It was found that the potassium/sodium ratio in the urine becomes high within two hours of exposure to a temperature of 40 C As this ratio rises, the antidiuretic hormone concentration in the blood also rises Artificial acclimatization of sheep by the use of 0 15 mg of desoxycorticosterone acetate per kilogram of body weight intramuscularly did not produce antidiuretic hormone at rest in a neutral environment (22 C), but, on heating, these animals were found to have high levels of antidiuretic hormone in the plasma This action lasts for about one day, and after that, heat, again, in winter produces no antidiuretic hormone It appears that the salt-saving hormones, which appear earlier than antidiuretic hormone in the hot season, prepare the cells by increasing intracellular sodium and decreasing the intracellular water so that there is a more facile release of water-saving hormone

In the northern parts of Australia there is a 30% reduction in conception during summer as compared to winter Comparison of data from towns of similar population in the north and south of the country showed lower reproductive rates in man in the hot region than in the cooler parts of the south Among sheep and cattle in the tropical regions there is a low rate of reproduction In the tropical pasture lands, conception rarely occurs in more than 60% of the ewes and cows In rats and rabbits, it has been found that large numbers of fetuses resorb if the animal is maintained at a temperature of about 35 C Analysis of this fetal resorption has shown that supplementary thyroid hormone, increased protein and vitamin intake, or supplementary progesterone can save a certain number of fetuses from resorption Acclimatization, however, appears to be the most satisfactory means of protecting the fetus even though the number of ovulations is reduced by acclimatization for one month at 35 C The protection afforded by acclimatization is completely overcome by injections of 2 mg a day of cortisone It appears that excessive mobilization of cortisone or 17-hydroxycorticosterone may account for fetal resorption Such resorption has been observed in sheep also, and it may be that the human fetus may be resorbed in the early stages of gestation if the mother is exposed to high ambient temperatures Temperatures up to 43 C occur in the summer in the Australian tropics

Hypophysectomy in Man —At the same meeting, Dr J A James and co-workers of the Neurosurgical Unit of the Dunedin Hospital reported a series of 21 patients with disseminated mammary cancer who were subjected to hypophysectomy There were three operative deaths Two patients with cancers arising during pregnancy were not influenced by the procedure Several patients were followed up for only a short time, but two patients survived for over a year There is often great relief from pain in those with bony metastases Cutaneous deposits tend to heal There is portion of severe cases among all children under 7 years of age was consistently higher in patients with chronic sinusitis than in those without the disorder Of the 2,838 children under 5 years of age in the investigation, 1,184 were mainly breast-fed Over the whole five-year period the incidence of mild cases was 36 4% of breast-fed patients and 29 7% of bottle-fed patients—a statistically significant difference It could not be shown that a history of measles in the mother had any additional effect on the protection given by breast feeding For all breast-fed patients under 5 years of age, the percentage of mild attacks among children whose mothers had had measles was lower (36%) than among those whose mothers had not had measles (40%)

The report concludes that the routine use of sulfonamides in the early stages of measles does not uniformly lower the incidence of complications It lowers the rate for acute otitis media in older children and in those with chronic sinusitis, and it is especially valuable in those with a past history of otitis media On the other hand, it does nothing to reduce the rate of severe pulmonary complications and may be a factor in raising this rate, especially in children under 2 years of age or in others with a mild attack In other words, there is no evidence to suggest that either sulfonamides or antibiotics are of prophylactic rather than curative value

Doctor or Mister—A protest against the traditional British custom of referring to a surgeon as "Mister" and not 'Doctor" is registered in a scholarly article by Dr George Graham (*Lancet* 1 264, 1957), who says that this curious practice, which does not exist in any other country, seems to arise from the old antagonism between the Royal College of Physicians and the Barber Surgeons Company after its formation in 1540 The members of the company rarely, if ever, had a degree of doctor of medicine, and their general education was certainly inferior to that of the physicians Furthermore, in those days the surgeons were under the domination of the physicians Now that the standards for physicians and surgeons are the same, it is strange that the distinction should still exist This practice causes much confusion among patients and the general public who cannot understand why a properly qualified doctor should not be so called It also causes inconvenience to themselves if they travel in countries where all medical men are called "Doctor"

Portacaval Anastomosis—In the *Lancet* (Jan 12, 1957) R M Walker states that the indications for portacaval anastomosis are hemorrhage from esophageal and gastric varices resulting from intrahepatic venous obstruction and the risk of such hemorrhage when large varices are known to exist Contraindications to the operation are the presence of severely impaired liver function and a portal vein unsuitable for anastomosis To determine the site of venous obstruction, transsplenic portal venography is used as a routine procedure Of a series of 56 patients, on each of whom end-to-side portacaval anastomosis was performed, 53 survived the operation In each of the 50 of those who had not had a previous portal venous system operation, there was no recurrence of the hemorrhage The most serious drawback of the operation was neuropathy, which may complicate a portal vein shunt Transient symptoms were the usual complication, occurring in 20% of the patients and ranging from mental disorientation to coma, and could be precipitated by taking a large protein meal In no patients there was no evidence of deterioration of liver function during the follow-up period, which in some cases was five years Thus, portacaval anastomosis has an important place in the management of portal hypertension

The Elderly Disabled—Many older persons admitted to the hospital have nowhere to go on discharge but many have some degree of disability, thus they are forced to stay in the hospital Their beds are urgently needed, and the cost of keeping these patients hospitalized is from $33 to $43 a week The administrative gap between the National Health Service and the National Assistance Act is responsible for this situation Since World War II a great deal had been done for older people, including the setting up of [illegible] geriatric units and 900 residential homes The home-nursing service made 12 5 million visits a year to the elderly A survey made on behalf of the Ministry of Health led to the conclusion that, if greater coordination of the efforts of hospitals, physicians, and welfare officers with welfare and local authorities could be made, more efficient use of the available services would ensue Thus, by additional home help, a number of hospitalized patients might return home, releasing much-needed beds

Recurrent Goiter—Piercy and Lange (*Lancet*, Jan [illegible] 1957) report that of 3,500 patients seen at the thyroid clinic, 118 had true recurrence of goiter or thyrotoxicosis after thyroidectomy had been performed Several were found to be in a hypothyroid state with hypertrophied remnants of gland due to stimulation by thyrotropic hormone These patients were treated successfully by thyroid extract The treatment of recurrent goiter is difficult, and radioactive iodine has a useful place in the regimen, but, even so, only 17 of the true recurrences were treated with it Its main use has been in patients with associated vocal cord disorders in whom tetany was a complication of the operation and in whom cardiovascular involvement contraindicated operation Many so-called recurrences are the continued growth of adenomatous tissue left behind from an earlier operation The authors recommend inspection of the entire gland at the first operation The inferior thyroid arteries should always be ligated, as this is a potent factor in preventing recurrence The ligations are carried out in continuity, the artery being found by deliberately exposing the carotid artery At operation, any pyramidal lobe and all obviously pathological tissue must be removed If the remnants left behind consist of healthy secretory thyroid tissue, sufficient thyroid hormone for the body will be produced, if the remnant is only the compressed rim of the thyroid gland, all will be well The authors believe that most recurrences are preventable

CORRESPONDENCE

AMERICAN ACADEMY OF PEDIATRICS AS POISON FIGHTERS

To the Editor —The special report "Pursuing the Killers," in THE JOURNAL, Jan 12, page 114, in describing the intense professional as well as lay organized activity to combat chemical poisoning—much of it accidental and in children—mentioned "the American Association of Pediatrics" as "a pioneer poison fighter This typographical slip gives me an opportunity to identify the organization by its correct name, the American Academy of Pediatrics, and to add a brief comment to show that the American Academy of Pediatrics could more properly be credited as "the" pioneer poison fighter The academy is responsible for initiating and continuing to furnish the necessary motive power through ideas and organization not only to make possible the wide range of professional and lay organized activity described in the article but to keep the movement in high gear

The academy in 1950 created a committee on accident prevention One of the first acts of the committee was a fact-finding survey of accidents seen in pediatric practice This study revealed that accidental poisoning was very common It was found that physicians wanted help, especially information on the toxic properties of common household agents and the treatment of poisoning The committee conceived the idea of establishing poison information centers in community hospitals and developing a manual which would furnish information to the practicing physician As a member of the committee, Dr Edward Press, who was then in Chicago, was asked to take responsibility to develop this project Through his initiative and imagination, the Illinois chapter of the American Academy of Pediatrics sponsored the first poison control center This demonstration was made possible by the assistance of the Chicago Board of Health, the cooperating hospitals, the staff of the American Medican Association's Committee on Pesticides, and other Illinois groups

The Academy of Pediatrics accident prevention committee was also responsible for the statement which first called attention to the frequency of aspirin poisoning in children and suggested measures to reduce this hazard This later became a joint statement of the American Medical Association Committee on Toxicology and the American Academy of Pediatrics, and was adopted voluntarily by representatives of the pharmaceutical industry at a meeting sponsored by the Food and Drug Administration

In 1955 the accident prevention committee of the academy prepared the first reference guide to the chemical constituents of common household substances together with treatment recommendations for children This was written by Dr Press and was field-tested in the poison control centers which soon sprang up after the Chicago demonstration The first edition of the manual "Accidental Poisoning in Childhood" was printed through a grant to the Academy of Pediatrics from Johnson & Johnson of New Brunswick, N J Copies of the publication are available through the American Academy of Pediatrics, 1801 Hinman Ave Evanston, Ill

The article in THE JOURNAL referred to the prospect of establishing a clearing house for the exchange of vital information from various poison control centers I am happy to report that, through the efforts of the American Academy of Pediatrics, the American Public Health Association, and the American Medical Association, the Department of Health, Education, and Welfare has recently announced the establishment of a national clearing house in the accident prevention unit of the United States Public Health Service

In closing, I should point out that the tremendous work done on this poisoning problem in all parts of the country and the creation of, at the present time, 44 poison control centers is not a spontaneous development but can be traced to a large degree to the state committee organization of the Academy of Pediatrics The state chairmen of the Academy of Pediatrics in virtually every state have set up state accident prevention committees Since the purpose of Medicine at Work is to call attention to the public spirit of American physicians, I would like to point out that these enthusiastic and dedicated pediatricians on state committees exemplify the highest ideals of American medicine Their work has been done largely through their state and county medical society memberships and their participation in the affairs of service clubs, the Parent-Teacher Association, and other child health and safety groups Thus the concern of these physicians to reduce accidents in children has become "a program"—and properly so—of these local groups When we consider what has been accomplished in preventing deaths from accidental poisoning in children in the past seven years as well as in reducing other accidents in children, we must give a full measure of credit to the efforts of all these physicians who work unsung at the community level

GASTROINTESTINAL HEMORRHAGE AND DRUGS

To the Editor —Dr Irving Brick in his paper "Early Diagnosis in Massive Upper Gastrointestinal Hemorrhage," which appeared in THE JOURNAL, April 6, page 1217, has commented on the importance of salicylates as a cause of gastrointestinal bleeding particularly in patients with peptic ulcer

The significance of this relationship is emphasized by two recent publications on the subject Brown and Mitchell (*Gastroenterology* 31 198-203 [Aug] 9) stated that hemorrhage followed the ingestion cyl compounds in 69 5% of their series of pa bleeding duodenal ulcer Interestingly portion of severe cases among all children under 7 years of age was consistently higher in patients with chronic sinusitis than in those without the disorder. Of the 2,338 children under 5 years of age in the investigation, 1,184 were mainly breast-fed. Over the whole five-year period the incidence of mild cases was 36.4% of breast-fed patients and 29.7% of bottle-fed patients—a statistically significant difference. It could not be shown that a history of measles in the mother had any additional effect on the protection given by breast feeding. For all breast-fed patients under 5 years of age, the percentage of mild attacks among children whose mothers had had measles was lower (36%) than among those whose mothers had not had measles (40%).

The report concludes that the routine use of sulfonamides in the early stages of measles does not uniformly lower the incidence of complications. It lowers the rate for acute otitis media in older children and in those with chronic sinusitis, and it is especially valuable in those with a past history of otitis media. On the other hand, it does nothing to reduce the rate of severe pulmonary complications and may be a factor in raising this rate, especially in children under 2 years of age or in others with a mild attack. In other words, there is no evidence to suggest that either sulfonamides or antibiotics are of prophylactic rather than curative value.

Doctor or Mister.—A protest against the traditional British custom of referring to a surgeon as "Mister" and not "Doctor" is registered in a scholarly article by Dr. George Graham (*Lancet* 1:264, 1957), who says that this curious practice, which does not exist in any other country, seems to arise from the old antagonism between the Royal College of Physicians and the Barber Surgeons Company after its formation in 1540. The members of the company rarely, if ever, had a degree of doctor of medicine, and their general education was certainly inferior to that of the physicians. Furthermore, in those days the surgeons were under the domination of the physicians. Now that the standards for physicians and surgeons are the same, it is strange that the distinction should still exist. This practice causes much confusion among patients and the general public who cannot understand why a properly qualified doctor should not be so called. It also causes inconvenience to themselves if they travel in countries where all medical men are called "Doctor."

Portacaval Anastomosis.—In the *Lancet* (Jan. 12, 1957) R. M. Walker states that the indications for portacaval anastomosis are hemorrhage from esophageal and gastric varices resulting from intrahepatic venous obstruction and the risk of such hemorrhage when large varices are known to exist. Contraindications to the operation are the presence of severely impaired liver function and a portal vein unsuitable for anastomosis. To determine the site of venous obstruction, transsplenic portal venography is used as a routine procedure. Of a series of 56 patients, on each of whom end-to-side portacaval anastomosis was performed, 53 survived the operation. In each of the 50 of those who had not had a previous portal venous system operation, there was no recurrence of the hemorrhage. The most serious drawback of the operation was neuropathy, which may complicate a portal venous shunt. Transient symptoms were the usual complication, occurring in 20% of the patients and ranging from mental disorientation to coma, and could be precipitated by taking a large protein meal. In most patients there was no evidence of deterioration of liver function during the follow-up period, which in some cases was five years. Thus, portacaval anastomosis has an important place in the management of portal hypertension.

The Elderly Disabled.—Many older persons admitted to the hospital have nowhere to go on discharge. Yet many have some degree of disability, thus they are forced to stay in the hospital. Their beds are urgently needed, and the cost of keeping these patients hospitalized is from $33 to $43 a week. The administrative gap between the National Health Service and the National Assistance Act is responsible for this situation. Since World War II a great deal had been done for older people, including the setting up of 70 geriatric units and 900 residential homes. The home nursing service made 12.5 million visits a year to the elderly. A survey made on behalf of the Ministry of Health led to the conclusion that, if greater coordination of the efforts of hospitals, physicians, and welfare officers with welfare and local authorities could be made, more efficient use of the available services would ensue. Thus, by additional home help, a number of hospitalized patients might return home, releasing much-needed beds.

Recurrent Goiter.—Piercy and Lange (*Lancet,* Jan. 26, 1957) report that of 3,500 patients seen at the thyroid clinic, 118 had true recurrence of goiter or thyrotoxicosis after thyroidectomy had been performed. Several were found to be in a hypothyroid state with hypertrophied remnants of gland due to stimulation by thyrotropic hormone. These patients were treated successfully by thyroid extract. The treatment of recurrent goiter is difficult, and radioactive iodine has a useful place in the regimen, but, even so, only 17 of the true recurrences were treated with it. Its main use has been in patients with associated vocal cord disorders in whom tetany was a complication of the operation and in whom cardiovascular involvement contraindicated operation. Many so-called recurrences are the continued growth of adenomatous tissue left behind from an earlier operation. The authors recommend inspection of the entire gland at the first operation. The inferior thyroid arteries should always be ligated, as this is a potent factor in preventing recurrence. The ligations are carried out in continuity, the artery being found by deliberately exposing the carotid artery. At operation, any pyramidal lobe and all obviously pathological tissue must be removed. If the remnants left behind consist of healthy secretory thyroid tissue, sufficient thyroid hormone for the body will be produced, if the remnant is only the compressed rim of the thyroid gland, all will be well. The authors believe that most recurrences are preventable.

GASTROINTESTINAL HEMORRHAGE AND DRUGS

To the Editor —Dr Irving Brick in his paper 'Early Diagnosis in Massive Upper Gastrointestinal Hemorrhage,' which appeared in The Journal, April 6, page 1217, has commented on the importance of salicylates as a cause of gastrointestinal bleeding, particularly in patients with peptic ulcer

The significance of this relationship is emphasized by two recent publications on the subject Brown and Mitchell (*Gastroenterology* 31 198-203 [Aug] 6) stated that hemorrhage followed the ingestio cyl compounds in 69 5% of their series of pa bleeding duodenal ulcer Interestingly (seven) of their patients with perforated peptic ulcer had a history of salicyl intake Kelly (*Am J M Sc* 232 119-128 [Aug] 1956) reported that 20% of a series of patients with bleeding peptic ulcer were receiving salicylates when symptoms developed He also pointed out that the records of 32% of 49 patients with unexplained upper gastrointestinal bleeding revealed a history of salicylate therapy in progress for various conditions when the bleeding occurred

Findings such as mentioned above should alert the practitioner to the fact that salicylates must at all times be prescribed with caution and must be avoided in patients with gastrointestinal distress

EXPLOSIONS IN OPERATING ROOMS

To the Editor —In the summary in THE JOURNAL (Foreign Letters, Nov 3, 1956, page 1001) of the report of a working party on anesthetic explosives, there are errors in the passage about operating theater floors which give the impression that such floors should be nonconducting It is suggested that the words "without such floors' should read "with such floors 'a new, nonconductive floor should read "a new, conductive floor, and "nonconducting paint" should read 'conducting paint" The whole passage would then read

"Only 5-10% of operating rooms in Great Britain have nonconducting floors (rubber or cork) In operating rooms with such floors the danger of explosion can be decreased by dampening the floor or by putting a damp sheet down if evaporation is rapid If explosive anesthetics are used routinely, the only safe procedure is to lay a new, conductive floor The use of conducting paints for floors is being investigated

This summarizes accurately the findings of the working party on the subject

RADIOACTIVE FALL OUT OVER CITY

To the Editor —In THE JOURNAL, March 9, page 803, Heise and Heise have suggested that a city may well offer an added measure of safety from radioactive fall-out I disagree with their meteorological interpretations and would like to explain my objections

They argue that the rising currents over a warm city account for the lower spore and mold concentration on the leeward side of the city However, since a city is not a source of spores and molds, it is difficult to distinguish between their explanation and a simple decrease in concentration farther from the source Besides, the fall velocity of radioactive particles in the first few hundred miles from a nuclear explosion is from 10 to 1,000 times greater than that of spores, molds, or pollen The slight upward current over a city which might support spores, etc , will have no important influence on such rapidly falling radioactive particles Heise and Heise's experiment in which a heated area in a small box simulated a warm city is unrealistic The horizontal wind in nature will disturb the simple convective cell of the experiment Further, as just noted, the lycopodium spores used by them fall at negligible rates compared with real radioactive particles of close-in fall-out

I can report an experiment relevant to fall out over cities At many places over the United States, the Weather Bureau operated fall-out collectors at ground levels for the Atomic Energy Commission both within cities and at nearby airports We find no systematic difference which would suggest an ameliorating influence of the city

There is no doubt that a city disturbs air flowing over it, but the upward currents which might ward off radioactive danger are too weak to influence the descent of large fall-out particles No significant meteorological benefit is believed to accrue from the city's warmth On the other hand, the city may still be safer during and after fall-out than the nearby countryside because of the availability of shielding and decontamination facilities, as well as avoiding problems of evacuation

POSTPARTUM ELECTROSHOCK THERAPY

To the Editor —The article on electroshock therapy during the puerperium, by Impastato and Gabriel, as published in THE JOURNAL, March 23, page 1017, prompted this submission In July, 1947, because of necessity I gave electric shock therapy to a 23-year-old patient on the eighth day after cesarean section It was necessary to use 1 Gm of amobarbital sodium intravenously every eight hours after delivery to alleviate the symptoms of excitement and hyperactivity Finally, on the eighth day after surgery, with the use of curare intravenously electric shock therapy was started and given daily for eight days, with a good result in the alleviation of symptoms

A review of my records indicates that I have had to use electric shock therapy as an emergency measure for the control of symptoms in eight patients during the period of gestation I have given electric shock therapy to one patient during the eighth month of pregnancy, to two patients during the seventh month, to three patients during the sixth month, and to five more patients who were less than six months pregnant

I was the first practicing psychiatrist in Arkansas to use electric shock therapy on private patients, and decisions had to be made because of emergency measures My records for the past 10 years include the treatment of 12 patients with postpartum psychoses who received shock therapy between the 5th and 15th days after delivery of the child

MISCELLANY

REPORT TO THE CHAMBER OF COMMERCE OF THE UNITED STATES AND THE NATIONAL ASSOCIATION OF MANUFACTURERS

William L McGrath

In January, 1956, the directors of the Chamber of Commerce of the United States adopted a resolution on continued Chamber participation in the International Labor Organization The board of directors of the National Association of Manufacturers did likewise in February, 1956 Both resolutions made clear that future participation in the ILO was contingent upon future developments For example, the NAM resolution reads, "If no change for the better in the activities and structure of the ILO is effected in the course of the 1956 sessions, the NAM will withhold its participation in the nomination of members for the 1957 delegation"

Has any "change for the better" been effected during the 1956 ILO sessions? This report is submitted in answer to that question

Major Issue

The major issue before the ILO in 1956 is increased communist participation The issue is in fact broader than communism, as it embraces socialism and nationalization of industry as well It so overshadows other considerations that this report will be limited to that subject

You may recall that at the March, 1955, meeting of the ILO governing body, instead of approving (as had been proposed) an amendment to the ILO constitution which if adopted might disqualify communist so-called employer and worker delegations, the governing body authorized the appointment of a committee (McNair committee) to study and report on the extent of freedom of employers and workers' organizations from domination and control by their governments No further action on the communist issue was taken, pending completion of the McNair report At the June, 1955, conference "tripartite delegations" from eight communist countries attended and participated This brings us up to 1956

March, 1956, Meeting of the ILO Governing Body

The McNair report was completed in February, 1956 At its March, 1956, meeting the governing body decided that, although there might be an exchange of views on the report at the June, 1956, conference, it would not be officially considered until the November, 1956, governing body meeting

June, 1956, Conference

At the June, 1956, conference a challenge to the credentials of communist so-called employers was for the second time rejected by the conference (the first time was in 1954) and tripartite delegations from nine communist countries attended and participated (Roumania had meanwhile been admitted)

In his report on this conference, Charles H Smith Jr, who served as the U S employer delegate, stated 'In all honesty, I cannot report any major improvement in the ILO itself as evidenced at the 1956 Conference' In a letter to Mr Mitchell, Secretary of Labor, dated Oct 10, 1956, Mr Smith said 'It is my belief that the United States cannot afford to continue to participate in ILO activities unless we take immediate concerted action to counter the socialistic and communistic propaganda that is so widely distributed at any ILO meeting

As you can see from the following, the likelihood of any such concerted action is remote indeed

Meetings in Washington

On Oct 17 I wrote Mr Wilkins, Assistant Secretary of Labor, suggesting that, in view of the importance of the forthcoming discussion of the McNair report at the November governing body meeting, it might be desirable to hold a conference on the subject

On Oct 22 I attended such a meeting, at which were present representatives of the Labor, State, and Commerce Departments They asked me what I intended to do at the governing body meeting I told them that above all else I intended to press for an amendment to the ILO constitution, which, if adopted, would exclude communist so-called employers from participation in the ILO I asked them what government intended to do, and they said they did not know

A second meeting was held in Washington on Nov 7 Mr Wilkins was present at this meeting, and also Mr Delaney, U S worker representative on the governing body I restated my position, but urged that government should take the lead in standing on the principle that the integrity of the ILO has been violated and that the constitution should be amended I was told that the government 'felt reluctant' to take such a position, but that as a matter of fact it as yet had no position on the McNair report

November, 1956, Governing Body Meeting

At this meeting discussion of the McNair report overshadowed all other issues The substance of the report (although almost 2,000 pages long) can be summed up as follows Although in some countries employers are in fact government men, and unions merely instruments of government, nevertheless in the interest of universality this situation may as well be accepted

The main importance of the report is that it discloses the growing extent of nationalization of industry in practically every part of the world except the United States

Early in the debate on the report the free employers took definitive action On the basis of facts disclosed in the report they introduced the following resolution, which was in substance identical with a resolution which originally had been proposed by the workers' group at the November, 1954, meeting of the governing body 'The Governing Body decides to place on the agenda of the 1957 Session of the International

---

United States Employer Representative to the International Labor Organization Governing Body

Labor Conference the amendment of Article 3, paragraph 5, of the Constitution so as to ensure that worker and employer representatives can only be appointed after nomination by organizations of workers and employers which are free and independent of their governments '

Such an amendment would disqualify communist so-called employer delegations I spoke in support of this resolution Copy of my address is attached hereto (see page 327), and I refer you to that text for a full explanation of the basic issue involved

All 10 employer members stood solidly in favor of the resolution and spoke eloquently on its behalf But we were assailed by a barrage of opposition oratory from the worker and government side, that revealed as never before the hopelessness of the free employer's position in the ILO

The labor-government-socialist majority, now well in control, openly, triumphantly, and even jeeringly displayed their satisfaction in riding roughshod over the free employers and relegating free enterprise to a secondary position in the ILO

We were told that nationalization of industry was on the march the world over, and we must therefore accept communist government agents as employers This argument was advanced chiefly by socialist worker and government members of the governing body, which has only one communist member In supporting the communist cause the socialists were protecting their own right to send government men from nationalized industries to the ILO as employer representatives

As an example of the brotherhood between socialism and communism, it was actually proposed that there should be two classes of employers within the ILO—free employers representing private enterprise, and communist and socialist employers representing nationalized industries This led to speculation as to whether there might be two classes of workers in the ILO—one representing free trade unions, and the other representing government-run unions serving in fact as agents of the state

The only supporter of the free employers was the government of Free China! Here is the vote

For the resolution	
All employer members of the governing body	10
The government of Free China	1
	11
Against the resolution	
All worker members of the governing body	10
All government members except Free China	19
	29

The governing body consists of 20 governments, 10 employers, and 10 workers

Mr Delaney, the U S worker member, said he was in favor of the resolution but was voting against it because he knew it would have no chance of passing The U S government spoke and voted against the resolution

After the defeat of the resolution it was proposed by Mr Delaney that the ILO should set up machinery in the office to investigate further the extent of freedom of association in member countries The proposal was broadened to include investigation of "methods of working" of the conference, including committees, and was then approved by the governing body

All that happened was that upon one investigation, that had lasted a year and a half, there was superimposed another investigation that will drag into years Absolutely nothing was done to resolve the issue involved

Conclusions

The above action dramatized the fact that the tripartite structure of the ILO has long since become a myth Besides government in the government group, we now have government in the employers' group and government in the workers' group The ILO is now to all intents and purposes an international government organization run mainly along political lines under the domination of advocates of collectivism, with free employers possessing no influence of any consequence and serving chiefly as whipping boys for the communists and the socialists

When the views of the free employers of the world no longer carry any appreciable weight in the ILO—when the socialist-communist government and labor majority in the ILO announce that free employers must "coexist' with communist agents in ILO employer committees—when governments invade both the employer and worker groups, and make a mockery of tripartite representation—when further nationalization of industry is openly announced as a desired goal—why should the NAM and the U S Chamber continue to participate in the ILO?

I believe we can accomplish far more outside the organization than we can within it As long as we stay in the ILO, we must carry its label Do we not participate in its meetings and its findings? How can we condemn something of which we are a part? But if we withdrew from the ILO, we could label it for what it is We could explain to the world that we are opposed to the majority philosophy of the ILO, that we do not believe in it, that we stand for free competitive enterprise instead of socialism and communism

Our dramatic action would arouse sufficient interest so that we could tell the story of what has happened to the ILO, and it would be listened to, both at home and abroad We could announce that we proposed to have nothing further to do with a communist-socialist dominated organization devoted to the cause of nationalization of industry

We would be helping the free employers of other countries They are too afraid of their governments, or too committed to personal careers within the ILO to get out of it But we are free We can take an action that they will envy—and perhaps our courage may help them to do likewise

And finally, withdrawal by the NAM and the U S Chamber, on the ground that we will not sit with communist agents as employers, will support the action taken by the Senate of the United States on April 19, 1956, when it passed a resolution denying any increase in ILO appropriations as long as communist delegates allegedly representing employers and workers are allowed to vote in the ILO

The U S government will no doubt press us, as they have before, to stay in the ILO I am not impressed by government arguments Our government has assured me that they fully understand the extremely serious nature of the situation within the ILO, but they do absolutely nothing about it At the governing body meeting, not one single government came forward with a suggestion for a possible solution to the present dilemma Nothing is going to be done unless somebody takes action

Suppose the U S Chamber and the NAM should withdraw, and the government would then appoint an employer delegation from some other source Would that affect us adversely? I think not Our position would be simply that if someone else wants to sit with the communists, it is all right with us—but we do not want to

Recommendation

In view of all of the above, I recommend that, in accordance with resolutions previously passed, and in the light of the fact that there has certainly been no change for the better in the activities and structure of the ILO, the NAM and the U S Chamber no longer participate in the nomination of employer delegations to the ILO

Statement by W L McGrath, United States Employer Delegate in ILO Governing Body, November 20, 1956

I wish to support most emphatically the conclusive arguments presented by Mr Waline on behalf of the proposed amendment to the constitution of the ILO [*] I regard this amendment as essential to reaffirm a principle which has been inherent in the ILO constitution from the very beginning

The constitution states in paragraph 1 of Article 3, that, of the four delegates from each country, 'two shall be government delegates and the two others shall be delegates representing respectively the employers and the work-people of each of the members The constitution then goes on to say in paragraph 5 of Article 3 The members undertake to nominate *non-Government* delegates and advisers chosen in agreement with the industrial organizations, if such organizations exist, which are most representative of employers or work-people as the case may be, in their respective countries

The vital word in that paragraph is non-Government' This paragraph assumes that employer and worker delegates must be nongovernment Taken in conjunction with paragraph 1 of Article 3, there can be no possible doubt that such was the intent of the framers of the ILO constitution

But it was not pinned down in sufficiently definitive language How could the framers of the ILO constitution possibly have foreseen the sorry spectacle of such complete government domination over the affairs of men that in some nations free organizations of employers and workers would be nonexistent and the only voice allowed to speak would be the tyrannical voice of government?

And so, in the June 1954 conference, when the credentials of communist so-called employer and worker delegations were challenged, the constitution was found wanting The majority of the credentials committee claimed and the majority of the conference agreed, that there were no words in the ILO constitution that specifically stated that freedom of domination and control by governments must be a condition of employer and worker representation in the ILO

Gentlemen, that is exactly the point This is a deficiency in the wording of the constitution It is now proposed to correct that deficiency by inserting a paragraph which will specifically spell out what the framers of the constitution intended, and what the constitution as a whole has implied from the very beginning

Let me give you an analogy from the history of the United States The Constitution of the U S A , as originally ratified implied certain rights and freedoms But some of our statesmen said—this is not enough We cannot depend upon implication and interpretation alone We must get these things down in black and white so no one can get around them And so, as you know, we enacted 10 amendments to our Constitution which together are known as our Bill of Rights All these amendments did was to spell out specifically what everyone knew *had been the intent of the Constitution* from the beginning But the effect was an effectual safeguarding of rights and liberties for all time

For example, the United States Constitution as originally drafted implied freedom of religion and of the press But was mere implication sufficient protection? We decided it was not Therefore we added an amendment that states 'Congress shall *make no law respecting an establishment of religion or prohibiting* the free exercise thereof, or abridging the freedom of speech, or of the press Gentlemen, that was not a change It was simply an affirmation of original principles And that is exactly what is proposed in this case

The net effect of the proposed amendment to the ILO constitution is simply that of affirming the principle stated in paragraph 5 *of Article 3, that employer and worker delegates* shall be nongovernment

Let us stick to this basic point and not get involved with specious philosophical arguments having to do with universality —a term which incidentally, I have yet to find in the ILO constitution

What has brought this issue to a head is the brazen endeavor of the communist countries to foist government men upon us as representatives of employers and workers

Is there any doubt as to the facts with respect to this situation? Let me quote just two brief sentences from the opinion of Mr Justice Cornelius included in the McNair report As to unions in communist countries he states It appears clearly that under this system, the trade unions constitute an agency of the government As to directors of industrial undertakings in communist countries, Mr Justice Cornelius states It seems impossible to deny that their relationship with the government is one of direct subordination leaving no scope for freedom of action on their part

The communists have put forward the claim that the functions of managers in industrial undertakings in communist countries are practically identical with the functions of free employers Well, I recently received a copy of the June, 1956 issue of *Industry and Labor* published by the ILO, which contains a summary of the Reorganization of State Industry in Czechoslovakia I quote in part from this report 'The work of each state undertaking is directed by the competent minister in accordance with principles laid down by the government Each minister is required to allocate the tasks outlined in the state plan to the various undertakings administer and supervise their implementation of the plan direct the undertakings wage and capital investment policies and supervise the selection and allocation of supervisory and managerial staff The report then goes on to say that each undertaking has a manager Well what does he manage? I would say that he must manage to do what government tells him to do or else

Have we not had enough of this farce? After what has happened in Hungary, can anybody sustain the claim that there are free associations of workers or employers in communist dominated countries or that their so called employer and worker delegations to the ILO can possibly represent anything but government and the Communist Party?

Gentlemen let us secure the enactment of the proposed amendment, which will reaffirm the long-established structure of this organization By doing so, we are merely confirming the original intent of the framers of the ILO constitution

If, on the other hand, we fail to enact this amendment, we will have allowed the ILO constitution to lapse by default We will have given our consent to a violation of its principles and sacrificed our integrity upon the altar of political expedience We will stand before the world as a prime example of international hypocrisy, and earn the public disrespect which can only be the forerunner of disintegration

---

[*] The text is as follows The Governing Body decides to place on the agenda of the 1957 Session of the International Labor Conference the amendment of Article 3 paragraph 5 of the Constitution so as to ensure that worker and employer representatives can only be appointed after nomination by organizations of workers and employers which are free and independent of their governments'

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Prenatal Injuries Liability for Injuries to Embryo of Fetus —This was an action by a child for alleged tortious injuries sustained by her while she was an embryo or fetus in her mother s womb From a judgment for the plaintiff, reversed by the court of appeals, the plaintiff appealed to the Supreme Court of Georgia

The plaintiff contended that she received prenatal injuries when the automobile in which her mother, who at the time was about six weeks pregnant with the plaintiff, was riding was struck by an automobile negligently operated by the defendant The defendant demurred to the complaint on the ground that the plaintiff was not quick in her mother's womb at the time of the accident

The Supreme Court of Georgia pointed out that the statutes of that state give every person tortiously injured a right of action In fact it quoted one of its prior decisions to the effect that, where a child is born after a tortious injury sustained at any period after conception, he has a cause of action While we realize, continued the court, that cases such as this might present extreme difficulties as to proof, we are not concerned with that question here The petition alleges that the plaintiff who is now in life received prenatal injuries, caused by the alleged negligent operation of an automobile in which the plaintiff's mother was riding while pregnant, which resulted in the plaintiff's being born with a deformed right foot, right ankle, and right leg, and in passing upon the demurrer these allegations must be taken as true If a child born after an injury sustained at any period of its prenatal life can prove the effect on it of a tort, it would have a right to recover

Accordingly, the Supreme Court reversed the judgment of the appelate court and found in favor of the plaintiff *Hornbuckle v Plantation Pipe Line Company, 93 S E (2) 727 (Ga , 1956)*

Workmen's Compensation Compensability of Anxiety Neurosis —This was an action for a compensation award based upon an anxiety neurosis alleged to have arisen out of an industrial injury From an adverse decision the defendant appealed to the Supreme Court of Florida

In June, 1953, the claimant was injured in the course of his employment in the defendant s mill The injury, to his right leg, aggravated a condition of varicose veins that he had suffered in both legs for some years A thrombophlebitis that developed in his right leg and extended to his lung (a pulmonary embolus) was successfully treated A year later he was again treated for thrombophlebitis in the right leg, and a ligation of the saphenous vein was performed to prevent another pulmonary embolus In July, 1955, the compensation board found that the claimant was depressed, apathetic, and in constant fear that, if he resumed his usual employment as a millworker, the long periods of standing would cause thrombophlebitis in his left le and another pulmonary embolus therefrom It, therefore, held that the claimant's anxiety neurosis was under these circumstances, a compensable injury O appeal, the defendant contended that the claimant' neurosis was too remote from the injury to sustai an award

The Supreme Court of Florida said that the sol issue was whether or not the claimant was entitle to compensation for a disability caused by an anxiet neurosis When there has been a physical injury, th full disability, including the effects of the neurosis, i compensable It must appear, however, that the neurosis was the direct and immediate result of the industrial injury The casual connection of the neurosi with the accident must not be remote Here, sai the court, the claimant's neurosis did not result directly and immediately from his injury The Commission had reasoned (*a*) that the injury was to claimant' right leg, (*b*) that the thrombophlebitis develope by aggravation of a preexisting disease, (*c*) that th thrombophlebitis resulted in a disease known as pulmonary embolus, (*d*) that this pulmonary embolu resulted in a disease known as an anxiety neurosis The Supreme Court said that the industrial injur could not possibly result in the thing feared (a pulmonary embolus) because the saphenous ligation admittedly will prevent a pulmonary embolus fro developing as a result of a blood clot in his right leg While a court in doubtful cases resolves many doubt in favor of a claimant under the Workmen's Compensation Act, where the claimant's neurotic disabilit is only remotely related to the industrial injury, industry should not be required to bear the cost of th disability Therefore, the ruling in favor of the claimant was reversed *Superior Mill Work v Gabel, 89 So 2d 794 (Fla , 1956)*

Malpractice Hospital's Liability for Nonprofessiona Acts of Its Servants —This was an action for damage for burns alleged to have been caused by the negl gence of the defendant surgeon and the defendan hospital From a judgment in favor of the surgeon bu against the hospital, the hospital appealed to the Supreme Court of Iowa

The plaintiff entered the defendant hospital for a operation on her back, which was to be performed b the defendant surgeon When she was taken to th operating room, she was placed face down on the operating table and "preped' and draped for surgery Whil the 'preping was going on, the surgeon retired to th scrub room to scrub for the operation "Preping refer to the preparation of the skin in the surgical are including shaving, cleansing, and things of that natur The surgeon had the right to determine how plaintif would be "preped,' but he had given no special instructions in this instance and did not know what solutions were used in the final preparation When th surgeon returned to the operating room, he observe nothing objectionable about the "preping" and proceeded with the operation, which took four hour After the operation, a dressing was applied to the sur gical area, and the plaintiff was returned to her room The defendant surgeon did not see her again until the next morning When the surgeon saw the plaintiff the next morning, he expressed surprise as he observed the severe burns on her abdomen He said there had been no explosion during the course of the operation or in his presence, but he gave no explanation as to the cause of the burns The plaintiff tried to find out what happened, but nobody ever told her and no evidence was introduced at the trial to enlighten the court as to what happened According to the nurses' records, doctors expressed the opinion that the blisters were "apparently from ether"

The crux of the case, said the Supreme Court of Iowa, resolves itself around two main issues upon which this court has not previously made pronouncement and upon which there is little authority elsewhere The first issue, stated simply, is whether or not in cases of this nature it is necessary under the doctrine of *res ipsa loquitur* for plaintiff to prove what instrumentality or instrumentalities caused her injury, and the second is what liability a corporate hospital has for the acts or omissions of its officers, employees, or attaches when a patient under anesthesia is injured by lack of due care while in the hospital for treatment or surgery

The doctrine of *res ipsa loquitur*, said the court, is a simple understandable rule of circumstantial evidence with a sound background of common sense and human experience, and difficulty comes only when we attempt to transform it into a rigid formula, which arbitrarily precludes its application in many cases where it is most important that it be applied It is regarded as a presumption, throwing upon the party or parties charged with the duty of producing evidence of the circumstances, to come forth with the evidence, whether culpable or innocent, which is particularly accessible to him or them but inaccessible to the injured person In the instant case the plaintiff placed herself in the care and custody of the defendant surgeon and the hospital employees, and, from the time she lost consciousness until she awakened some nine and one-half hours later, she did not know what instrumentalities were used on her nor how she was injured The injury was of a kind that ordinarily does not occur in the absence of someone's negligence Whether the doctor or the hospital employees were then acting in a professional, semiprofessional, or nonprofessional capacity, she would not know She brought action against the surgeon in charge and properly assumed that, if the injury occurred during the operation proper, by him or his temporary assistants in a professional capacity, he would be liable, but, if the injury occurred while defendant hospital was undertaking to perform other nonprofessional or simple manual acts of an administrative nature through its servants, then, of course, the hospital would be liable It was sufficient that plaintiff disclosed that the injury resulted from an external force applied while she lay unconscious in the hospital, and we conclude that that satisfies the requirement that the plaintiff identify the instrumentality causing her injury It is as clear an identification as such a plaintiff of her own knowledge may ever be able to make, and, under the doctrine of *res ipsa loquitur*, the law should require no more We think, said the court, it is a just and logical conclusion that one who, while undergoing a surgical operation, sustains an unusual injury to a healthy part of her body not within the area of the operation, be not precluded from invoking the doctrine of *res ipsa loquitur* in an action against the doctors and nurses participating in the operation The same thing must be said of the corporate hospital regarding its preceding or subsequent care of the patient This is not altered by the fact that all the parties do not stand in such relation to one another that the acts of one may be regarded as the acts of the other and the injury may have been caused by the separate acts of any one of them, or by the fact that there were several instrumentalities and no showing as to which caused the injury or as to the particular defendant in control of it

The defendant hospital also contended that the 'preping services rendered by the surgeon, nurses, and house physician were professional services, that the defendant hospital could not practice medicine or osteopathy, and that, therefore it could not be responsible for injuries caused by such professional acts The evidence showed that the "preping had been done while the defendant surgeon was out of the operating room getting scrubbed up for the operation We are aware, said the court, that there are cases that hold that 'preping' is considered a part of the operation proper, and in some cases this may well be, especially where special 'preping' is required A careful study of the record in this case, however, fails to reveal that the 'preping done in this case was any more than the 'standard' procedure or simple manual act done by servants or students of the hospital, and, therefore, we do not feel called upon here to decide whether preping generally is in fact the practice of osteopathy and surgery The failure of hospital servants to do any such administrative or simple manual acts with due care would, of course, constitute negligence for which the principal may be held liable under the doctrine of *respondeat superior*, regardless of the servant s title, license, or professional position In the absence of proof that any tasks being performed, with the exception of those of the surgeon, were of a professional nature, they must be found to be administrative Clearly then, continued the Supreme Court, except when employees, regardless of class, were loaned or were engaged in the practice of osteopathy, this defendant hospital determined and directed their duties and made assignments With those exceptions, it had "complete' control over the doctors and nurses employed by it In such cases it seems only just and proper to require satisfactory proof by the master that its servant was not acting as its servant at the time or times in question Although it is true, the court concluded, that the professional discretion of hospital staff doctors cannot be controlled by the nonlicensed corporation, nevertheless even those individuals, while performing nonprofessional functions under the master-servant relationship, will not protect the corporation from liability for its servant s negligence

Other contentions of the defendant hospital were also overruled, and the judgment of the trial court against the hospital was affirmed *Frost v Des Moines Still College of Osteopathy and Surgery, et al*, 79 *N W (2d) 306 (Iowa, 1956)*

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Erosive Gastritis in Cirrhosis Influence of Portal Hypertension on the Gastric Mucosa E D Palmer Am J Digest Dis 2 31-36 (Jan) 1957 [New York]

The importance of acute erosive gastritis lies in the suddenness with which it may lead to exsanguination Among 38 cirrhotic patients with esophageal varices who died while under treatment by the author in the past 6 years as a direct result of hemorrhage, the hemorrhage was found to be originating from erosive gastritis in 4, from gastric or esophageal varices in 30, and from ulcer in the other 4 patients It has been assumed that the mechanical venous back pressure of portal hypertension rather than a circulating metabolite is at fault when erosive gastritis develops in patients with cirrhosis The reasons for this assumption are that there appears to be no correlation between the development of erosive gastritis and the degree of liver insufficiency and that erosive gastritis becomes rare after portal decompression The purpose of the present study was to investigate the histopathology of the gastric mucosa in patients with portal hypertension due to cirrhosis in an effort to determine whether mechanical capillary damage in the mucosa, secondary to venous hypertension, is a proper explanation for the erosive process Histological examination of the canine gastric mucosa after sudden production of portal hypertension by portal vein ligation shows that the increased venous pressure under these artificial conditions is reflected back into the vessels of the mucosa When portal hypertension develops naturally and gradually in cirrhosis of the liver, however, the hypertension is contained within the submucosa and no vascular dilatation develops within the mucosa

Degenerative gastritis with a prominent erosive element, leading to blood loss, is an important complication of cirrhosis with portal hypertension Both gastroscopically and histopathologically the gastritis appears entirely similar to that encountered in patients who have no liver or portal disease The most significant abnormality is necrobiosis of the mucosal neck stratum The blame cannot be placed on interstitial hemorrhage from the mucosal capillaries, nor can mucosal plethora with capillary stasis be considered an etiological factor The presence of venous dilatation in the submucosa suggests the possibility that secondary mucosal hypoxia, due to stasis without mucosal engorgement, might be sufficient, since it is known that the neck stratum is particularly susceptible to the hypoxic influence of ischemia Although this has by no means been proved, it seems a more acceptable explanation than the only reasonable alternative, that of the influence of a noxious circulating metabolite

A Contribution to the Clinical Study of Pigmentary Cirrhosis Report on 31 Cases M Girard, M Plauchu, J Fayolle and R Bastide J med Lyon 38 39 71 (Jan 20) 1957 (In French) [Lyon, France]

The authors report on 31 patients with pigmentary cirrhosis Pains in the right hypochondrium or in the epigastrium were present in most patients Dyspepsia, circulatory disturbances, gastrointestinal hemorrhage, and icteric episodes were neither frequent nor marked Splenomegaly, collateral circulation, and ascites were rare Melanodermia, which is a classic symptom of the disease, was not uniform in its cutaneous distribution or in its color intensity This symptom is latent in most patients and is often overlooked Diabetes that was mild but difficult to control and insulin instability were observed in 12 patients The curve of provoked hyperglycemia showed that some patients did not tolerate glucose More than half of the patients showed no signs of sexual impairment Major disturbances of the sexual organ were rare other endocrine disturbances were rare

Acute heart failure occurred in 2 patients under 50 years of age Latent or mild forms of cardiac insufficiency frequently associated with pigmentary cirrhosis were observed in patients in the "vascular age, only The diagnosis was based on the presence of hypertrophic cirrhosis and cutaneous pigmentation Biological and anatomic tests were given because of the monosymptomatic manifestation of the disease in most patients and because the pigmentation was latent in many cases Biological tests were considered positive only when the iron content of the serum was above 260 mcg Hormonal tests did not prove reliable Laparoscopy was the most frequently used test Needle biopsy was used when all other tests had given equivocal results

Hepatitis as Occupational Disease Among Physicians C Frieberger, M Haider, E Rissel and F Wewalka Wien klin Wchnschr 69 44-47 (Jan 18) 1957 (In German) [Vienna]

A questionnaire was sent to physicians and lawyers in Vienna, Lower Austria, and Burgenland in an attempt to ascertain the incidence of hepatitis in physicians (using the lawyers as controls) and to eval

---

The place of publication of the periodicals appears in brackets preceding each abstract

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals Requests for periodicals should be addressed Library, American Medical Association Periodical files cover 1948 to date only, and no photoduplication services are available No charge is made to members but the fee for others is 15 cents in stamps for each item Only three periodicals may be borrowed at one time and they must not be kept longer than five days Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them uate it with regard to the problem of occupational risks They were asked whether and when they had had jaundice that was not the sequela of gall bladder disease They were also asked about the time of the occurrence of the illness and its duration and whether it occurred simultaneously with active military service during the war Of the physicians, 29 7% had hepatitis after the age of 18 years, as compared to 22 9% of the lawyers An incidence of 16 8% was found among the physicians as compared to 8% among the lawyers, when cases occurring in the course of active military service during the war were excluded An incidence of 23 8% was found among medical specialists who still were working in hospitals when they received the questionnaire, as compared to 15 7% among general practitioners working in their offices and in hospitals

These data suggest that physicians are exposed to an increased occupational risk with regard to hepatitis and that this risk is even greater with hospital work It is emphasized that hepatitis is a reportable occupational disease in Austria and that the incidence of hepatitis exceeds that of other infectious diseases in the course of practicing medicine Prophylaxis of hepatitis has not received enough attention because of the long incubation period of homologous serum jaundice Comprehensive enlightenment of the physicians and the nursing personnel concerning the various possible ways of transmission of the viruses causing hepatitis and concerning the associated occupational risk is *indispensable*

Acute Recurrent Rhabdomyolysis (Paroxysmal Myohæmoglobinuria) A Report of Three Cases and a Review of the Literature D H Bowden, S H Jackson and N F Walker Medicine 35 335 351 (Dec) 1956 [Baltimore]

Although paroxysmal myohemoglobinuria was first described in 1910, only 25 cases have been reported since then, and the authors present observations on 3 additional cases The important data on all 28 patients are summarized The disease occurs in paroxysms that are heralded by muscle pains and weakness, followed shortly by the passing of dark red-brown urine The provisional diagnosis is made by demonstrating a hemoglobin-like pigment in the urine in the absence of hemoglobinemia, but absolute proof of the diagnosis depends on the spectroscopic identification of myohemoglobin in the urine Since the spectroscopic absorption bands of myohemoglobin are similar to those of corpuscular hemoglobin, the differentiation of the 2 pigments formerly required the use of expensive equipment Now a method has been developed that does not require such equipment Studies carried out by the authors indicate that the symptom complex of paroxysmal myohemoglobinuria is the result of a pathological process in striated muscle, and, in conformity with this concept, they propose that the condition be renamed 'acute recurrent rhabdomyolysis' Myohemoglobin is but one of many substances that are released from the muscles into the blood and excreted by the kidney There is no reason to suspect that there is any abnormality in the structure of the myohemoglobin liberated or that this substance is in any way implicated in initiating the attacks The term myohemoglobinuria describes a single feature only and in no way indicates the underlying pathological process

Since the authors observed 3 patients with this supposedly rare disease in the course of 2 years, they believe that it is perhaps more common than the number of reported cases indicates The disease causes widespread muscle damage, but seems to involve only striated muscles There are indications that 2 distinct forms of the disease exist In 1, the attacks are always precipitated by exertion, in the nonexertional type, acute attacks may be associated with a variety of factors or may appear spontaneously Genetic factors may operate, but the exact mode of inheritance has not been established Acute recurrent rhabdomyolysis is a serious disease Repeated attacks are to be expected, there may be residual atrophy of muscles, and the condition is sometimes fatal

Carbon Tetrachloride—An Underrated Hazard G E Joron, C H Hollenberg and E H Bensley Canad M A J 76 173-175 (Feb 1) 1957 [Toronto]

Carbon tetrachloride can produce fatal liver damage, but in the last 15 years it has been shown that the most common lesion in poisoning with this solvent and dry cleaning agent is acute injury to the tubules of the kidney producing acute renal failure or lower nephron nephrosis The terms acute renal failure or acute tubular injury are to be preferred to lower nephron nephrosis Poisoning with carbon tetrachloride may follow its inhalation, ingestion, or absorption through the intact skin Ingestion of alcohol before, during, or soon after exposure greatly increases the likelihood of renal damage The histories of 12 patients with poisoning due to carbon tetrachloride are presented In the first 8 of these, there was exposure to alcohol as well as to carbon tetrachloride, severe renal damage followed in every instance In the remaining 4 patients, there was no ingestion of alcohol and no renal damage None of the 12 patients had serious hepatic involvement

A patient who has been exposed to carbon tetrachloride, particularly if there was concomitant alcohol ingestion, deserves close observation Nausea and vomiting may occur without evidence of involvement of the liver or kidneys Elevation of blood pressure level and back pain suggest renal involvement The early laboratory investigation should include examination of the urine, which in a typical case of acute tubular injury is scanty, has a specific gravity of from 1 010 to 1 015 and contains albumin and many red and white blood cells and casts Under these circumstances azotemia will be present Liver function should be studied by measuring the serum bilirubin and cephalin flocculation or by a similar test

These patients usually respond to conservative therapy and seldom need any form of dialysis However, they should be in a hospital where electrolyte studies can be carried out The principal danger is administration of excessive amounts of water and electrolytes during the phase of oliguria leading to death from pulmonary edema There are hazards in faulty diagnosis and treatment, but the greatest hazard is the lack of awareness of the dangers inherent in the use of carbon tetrachloride The main problem is prevention of exposure Carbon tetrachloride should not be sold without suitable warning labels, and the warnings should be strong enough to discourage its use in the household and small industries In many large industries less toxic compounds now replace carbon tetrachloride as a solvent and dry cleaner

Patients with Hyperglycemia Treated with Thioctic Acid G Schirosa and L Pagliaro Riforma med 71 32-35 (Jan 12) 1957 (In Italian) [Naples]

The authors report on the treatment with thioctic acid of 29 patients with hyperglycemia The drug was given 2 or 3 times a day always before meals, 2 patients received it orally, and the others received it either intramuscularly or intravenously The patients were divided into 2 groups The 1st group (13 patients) was treated with thioctic acid only in doses of from 50 to 70 mg per day The effect was evident on the 2nd day after starting this treatment The 2nd group (16 patients) was treated with from 30 to 60 mg of thioctic acid given daily in addition to insulin The drug had a beneficial effect on the blood sugar level of all patients, those with mild hyperglycemia became normal The combination of thioctic acid with insulin permitted reduction of the dose of insulin in patients with severe hyperglycemia The best results were obtained in patients with marked hepatic deficiency The thioctic acid increases the glycogen synthesis in the liver

Acute Respiratory Disease in University of Wisconsin Students A S Evans New England J Med 256 377-384 (Feb 28) 1957 [Boston]

A study of the records of the department of preventive medicine and student health at the University of Wisconsin revealed that over 2,000 students report yearly to the student clinic—an incidence rate averaging 171 cases per 1,000 students in the 6-year period studied Respiratory infections were the single most important cause of admission to the infirmary, accounting for almost 33% of all admissions The months of highest incidence were January, February, and March Nonbacterial respiratory infections outnumbered bacterial infections by 5 to 1 and were responsible for about 84% of all respiratory illness A diagnosis of infectious mononucleosis was made in 21 5% of all the patients with respiratory diseases

A study of the causation of acute respiratory disease in 290 university students ill enough to be admitted to the infirmary was made with the use of serologic techniques and HeLa-cell cultures for isolation Known infections thus established included adenovirus in 2%, streptococcic tonsillitis and pharingitis in 8 3%, influenza in 3 4%, herpetic infections in 1 3%, bacterial pneumonia in 1 6%, and psittacosis in 0 3% The cause of the respiratory disease thus was unknown in 83 1% of the 290 students A diagnosis of an adenovirus infection could not be made on clinical grounds Viruses of types 1, 3, and 4 were isolated Present evidence does not warrant immunization against adenovirus infections in such university students More data must be obtained for intelligent use of the vaccine in any civilian group Patients with streptococcic throat infections should receive penicillin therapy for 10 days to eradicate the organism and prevent rheumatic fever Antibiotic therapy of nonbacterial pharyngitis and tonsillitis is of no advantage and presents the hazards of toxicity or sensitization to penicillin or both

Symptomatology of Congenital Pulmonary Arteriovenous Fistula F Grosse-Brockhoff, F Loogen and H Vieten Deutsche med Wchnschr 82 134-137 (Jan 25) 1957 (In German) [Stuttgart, Germany]

The authors discuss the symptoms and signs of arteriovenous fistulas of the lung on the basis of observations of 9 patients with the congenital form of this disorder and of 1 patient in whom the fistula was probably of traumatic origin but who had symptoms similar to those of patients with the congenital form The 9 patients with congenital pulmonary arteriovenous fistulas were found among about 2,500 with congenital angiocardiopathies This pulmonary vascular anomaly is associated in some patients with a hardly detectable cyanosis, whereas in other patients the cyanosis is severe Anemia may be observed in some patients either as the result of hemorrhages from the lung or from mucosal telangiectases, and these conditions may obscure the existing cyanosis The great variability in the symptoms is illustrated by the fact that not one of them was present in all 10 patients Foci of increased density in the roentgenogram of the chest in association with the typical murmur caused by the fistula are the most important diagnostic features An erroneous diagnosis of tuberculosis may be made particularly if the fistula is located in the upper part of the lung Conversely, coexistent tuberculosis may make it more difficult to recognize an additional arteriovenous fistula Confusion with tuberculosis may occur whether there is a hemangioma-like anomaly or a well-defined direct fistula between artery and vein Auscultation may reveal no abnormality If the fistula is near the hilus, the roentgenogram of the lung may be normal It is demonstrated on the basis of a case history that in such cases the diagnosis can be established only by catheterization of the heart and by angiocardiography

Bronchial Asthma Treated with Phenylbutazone P Dell'Aera Riforma med 71 97-103 (Jan 26) 1957 (In Italian) [Naples]

The author reports on the results obtained in 3 groups of asthmatic patients treated with phenylbutazone The 1st group was composed of 28 patients with bronchial asthma and emphysema but good cardiovascular condition The 2nd group was composed of 2 patients with asthmatic bronchitis, marked emphysema, and cardiocirculatory insufficiency The 3rd group consisted of 20 patients, most of them young, with allergic asthma All patients received 0 3 Gm of phenylbutazone injected intramuscularly every 12 hours Other antiasthmatic drugs were not given An examination made 3 to 4 months after the treatment showed that the treatment was most beneficial to the patients of the 1st group, 16 patients had recovered completely, 10 had had some attacks but not as severe as those they had had before the treatment, the therapy failed in 2 patients The results obtained in the patients of the 3rd group were satisfactory The therapy had to be discontinued because of intolerance in the patients of the 2nd group Gastric disturbances occurred in 15, suppression of urination with a slight increase of blood sodium and chlorine levels in 3, and kidney disturbances in 5

Confusing the Issue Psychoses as Symptoms of Cancer T H Howell Practitioner 178 233 (Feb) 1957 [London]

Amid the senile and demented elderly patients there are some whose mental symptoms cloak bodily disease and confuse the issue until a postmortem examination establishes the diagnosis A recent series of autopsies revealed a group of patients with cancer whose obvious mental symptoms had only made confusion worse Their histories illustrate some of the peculiar problems in geriatrics The 6 patients whose case histories are briefly presented were all between 80 and 90 years of age Most of them were noncooperative and difficult to examine It is important to realize that in older persons with a new growth mental confusion can be the chief presenting symptom

Alcohol-Induced Pain Due to Carcinoma A H James, H R S Harley, E H Horton and F K Storring Lancet 1 299-301 (Feb 9) 1957 [London]

Although several workers have reported the occurrence of pain after the taking of alcohol in some patients with Hodgkin's disease, this phenomenon does not seem to have been reported in the presence of other neoplasms The authors present the histories of 2 patients with alcohol-induced pain due to carcinoma The 1st patient was a 47-year-old woman first seen in October, 1954 She described attacks of pain behind the upper part of the sternum after taking alcohol The 1st had been at Christmas, 1952, about five minutes after drinking three-quarters of a glass of port After a minute or 2 the pain became severe, and radiated around the root of the neck to the back and down both arms It subsided in about 20 minutes, but soreness persisted until the next day Between that occasion and her attendance at the hospital in October, 1954, she had taken alcohol 5 times, and each drink had caused an attack of pain identical with the 1st Roentgenograms showed a round opacity in the anterosuperior portion of the mediastinum The administration of alcohol by gastric tube or by vein produced the attacks of pain similar to those of which she complained The mediastinum was not explored because the tumor was presumed to be a manifestation of Hodgkin's disease A roentgenogram of the chest in March, 1956, revealed that the tumor was larger and better defined The administration of alcohol at this time (20 ml by stomach tube) caused only slight discomfort Later there was no pain after drinking 80 ml of gin

Uncertainty about the nature of the tumor led to exploration A hard mass was found infiltrating the front of the pericardium as well as the superior mediastinal structures behind the manubrium A globular extension of this mass on each side invaded the anterior margins of the two lungs The extension of the tumor that had invaded the right lung was resected, but the mediastinal part of the mass could not be removed The histological appearances of the tumor varied greatly in the sections examined Follicular collections of small round cells with abortive Hassall's corpuscles suggested that the tumor was of thymic origin as did the appearances at operation That the susceptibility to alcohol-induced pain disappeared while the tumor was enlarging has not been described before

The 2nd patient had been well until 2 months before she was hospitalized At that time she noticed aching across the front of her chest, gradually extending to her back, shoulders, and arms, her whole chest feeling "stiff and taut" These symptoms persisted and became steadily worse About 2 weeks after her pain started she noticed that alcohol, in the form of beer, stout, or wine, increased the severity of the pain For 4 weeks she had preferred to abstain rather than experience the acute exacerbation of pain that alcohol always caused The woman's condition became worse, and she died 13 days after admission Autopsy revealed a tumor infiltrating the pericardial sac and the left main bronchus and areas of growth in the left lung and in the pancreas, the tail of which was undergoing necrosis, small deposits of adenocarcinoma were found in the kidney Before concluding that alcohol-induced pain may occasionally be produced by any type of malignant tissue, the authors make 2 reservations In case 1 the tumor was probably of thymic origin Thomson has suggested that Hodgkin's disease is a disseminated carcinoma of which the primary growth is in the thymus Alcohol-induced pain in a patient with a thymic carcinoma might be held to support this hypothesis The 2nd patient had an adenocarcinoma, probably of pancreatic origin Alcoholism is among the recognized causes of acute pancreatitis

Studies on Anti-V A Recently Discovered Rh Antibody E R Giblet, J Chase and A G Motulsky J Lab & Clin Med 49 433-439 (March) 1957 [St Louis]

The new blood group antibody "anti-V," recently described by DeNatale and co workers (THE JOURNAL 159 247 [Sept 24] 1955) was found in the serum of 2 previously transfused patients The 1st patient was an elderly white man with severe hematuria and anemia His history included a leg amputation 10 years previously, with subsequent complications requiring the transfusion of 22 units of blood, several of which were Rh positive When admitted to hospital he received 8 units of blood, but death occurred rapidly It was because of difficulties observed in cross-matching that his blood was studied His erythrocytes were group A, the Rh genotype was R'r (Cde/cde) His serum contained both anti-D and anti-V The 2nd patient, a young white man with congenital nonspherocytic hemolytic anemia, was found on routine serologic study to have anti-D and anti-V in his serum His sensitization had occurred 12 years previously when he received 10 units of blood after a war injury Blood drawn from this patient was the source of anti-V used for studies concerning the racial distribution of the V antigen and its relation to the Rh blood group system, and for additional studies concerning the incidence, serologic nature, and destructive capacity of anti-V in vivo

Racial studies confirmed the previously reported high incidence of the V antigen in Negroes and its rare occurrence in white persons The antigen was also found to be unusual in orientals (Japanese or Filipinos) and American Indians Further confirmation was obtained for the hypothesis that the V gene is present only in chromosomes with the Rh genes c and e The occurrence of V with cDe is apparently more frequent than with cde The ability of the new blood group antibody to destroy erythrocytes in vivo was shown in the younger of the 2 patients It might, therefore, be responsible for hemolytic transfusion reactions The fact that the 3 examples of anti-V so far discovered—in the patient reported on by DeNatale and in the authors' 2 patients—have occurred in Rh(D)-negative persons is contrary to expectation and would appear to be more than coincidental Assuming that the only factor preventing the possible formation of anti-V is the presence of the V antigen, by far the most numerous candidates for making this antibody should be Rh-positive, V-negative recipients of Rh-positive, V-positive blood No such examples have been found To explain this discrepancy, at least 2 possibilities may be considered First, the V antigen, like C, may rarely cause an antibody response in Rh(D)-positive recipients If this were true, one would expect to find the antibody in those Rh-negative, V-negative persons who had been sensitized by the relatively uncommon blood from an Rh-negative, V-positive donor or by the more common blood from an Rh-positive, V-positive donor, the latter probably was the case in the authors' 2 patients A 2nd possibility is that anti-V has been found in the blood of Rh-positive persons but not recognized as such To reveal the presence of anti-V it would be necessary to absorb the serum with rr (cdef/cdef) V-negative cells, but studies of this type have not yet been carried out

Frequency of Partial Megaloblastic Erythropoiesis in Older Achylic Patients with Slight Anemia Iron, B_{12} and Vitamin C Content in Blood Dimorphic Anemia, Anemia with Multiform Pathogenesis, and Iron Treatment Diagnostic Significance J Pedersen, J Lund, A S Ohlsen and H P Ø Kristiansen Ugesk læger 119 1-14 (Jan 3) 1957 (In Danish) [Copenhagen]

Consecutive examinations in 1955 of the bone marrow in 46 patients, aged at least 50 years, with achylia refractory to histamine, slight anemia but otherwise no certain signs of pernicious anemia revealed beginning or partial megaloblastic erythropoiesis in 7 Comparison of the hematological data in 10 patients with partial megaloblastic erythropoiesis and 10 patients with achylia, total megaloblastic erythropoiesis, and marked anemia showed that, while the iron and vitamin C deficiency seemed to be equally marked in the 2 groups, the vitamin B_{12} deficiency was less in the 1st group The patients in this group seem to represent 2 clinical types, 1 with a beginning pernicious anemia complicated by iron and vitamin C deficiency, the other marked by anemia of other pathogenesis, most often a chronic nephrogenic hemolytic anemia intermittently complicated by toxic-infectious anemia due to medicamental intoxication and colibacteremia Diagnosis of megaloblastic erythropoiesis was made only when megaloblasts of classic type were observed Their appearance can apparently be accelerated by overcoming a present iron deficiency Intensive iron therapy was accordingly applied in cases in which diagnosis was uncertain, and diagnosis of megaloblastic erythropoiesis was made in this way in 3 cases Characteristic changes in the leukopoiesis, including macrometamyelocytes, can sometimes be seen in the marrow when typical megaloblasts are not yet present Examination of the sternal marrow is the most important method for establishing the diagnosis of partial megaloblastic erythropoiesis Treatment with vitamin B_{12}, iron, and vitamin C is beneficial but must be applied intensively, this is particularly true of iron, which must often be given intravenously at the start In uncomplicated cases normal blood values will often not be attained until after 6 months' treatment Iron deficiency in patients with partial megaloblastic erythropoiesis is ascribed not only to reduced resorptive ability but also to insufficient nutrition Presumably, older women with achylia are especially likely to be inadequately nourished

SURGERY

Vagal Resection in Treatment of Duodenal Ulcer A A MacKelvie Brit M J 1 321-323 (Feb 9) 1957 [London]

Of 473 patients (401 male and 72 female) between the ages of 10 and 79 years with duodenal ulcer, 118 underwent vagal resection alone, 332 vagal resection with gastroenterostomy, 19 vagal resection and pyloroplasty, and 4 vagal crush Of the 118 patients, 3 died —1 from anesthesia, 1 from secondary renal carcinoma, and 1 from aneurysm, and 10 were lost to follow-up Twenty-three of the remaining 105 patients required gastroenterostomy for symptoms secondary to vagal resection, such as gross gastric retention, with foul flatulence and diarrhea Six additional patients were awaiting gastroenterostomy Vagal resection alone, although it appeared complete, thus was a failure in 28% of the 105 patients Recurrence of duodenal ulcer occurred in 4 of the remaining 76 patients, and many others had flatulence, diarrhea, and uncomfortable fulness after meals Nine of the 332 whose primary operation consisted of vagal resection and gastroenterostomy died of the operation, an operative mortality of 2 7% Of the remaining 323, 7 died of intercurrent disease unrelated to the operation or ulcer and were free of dyspepsia to the date of death Ten were symptom-free, but they had been followed up for less than 1 year after the operation Eight patients were lost to follow-up Of the remaining 298, 238 (group 1) had no gastric symptoms, 31 (group 2) had very minor symptoms, 8 (group 3) had symptoms that were not preventable but which did not interfere with their activities, 13 (group 4) had symptoms preventing full enjoyment of life, and 8 (group 5) were therapeutic failures The 277 patients in the first 3 groups were well satisfied, they were no longer on a diet, and most of them had returned to their preoperative occupations

The 4 patients in whom vagal crush was done were therapeutic failures Excellent results were obtained in the 14 patients with vagal resection and pyloroplasty Operations on the vagal nerves alone, either by resection or by crushing, do not give good results in patients with duodenal ulcer Excellent results are obtained with vagal resection combined with posterior gastroenterostomy in more than 90% of the patients Equally good results may be obtained by vagal resection combined with pyloroplasty The results are at least as good as those after partial gastrectomy, and the operative mortality is probably appreciably lower These good results, added to the fact that partial gastrectomy is not excluded as a further possible operative treatment for failure in resistant cases, indicate that the combined operation should be the method of first choice in the treatment of patients with duodenal ulcer

Arteriovenous Fistulas in Young Patients with Chronic Obliterating Arteriopathies G Cadili Minerva chir 11 1121-1131 (Nov 30) 1956 (In Italian) [Turin, Italy]

A group of 143 patients with chronic obliterating arteriopathies were subjected to combined operation (gangliectomy, splanchnicectomy, hemiadrenalectomy, and in some arteriectomy) and/or to treatment with a "lytic cocktail," which in many patients made it possible to avoid or postpone operation Four to 8 years after the treatment most of the patients were still well, some had a relapse after from 1 to 3 years, and 13 patients had a relapse with pain more severe than before the treatment after a period of from 1 to 12 months Arteriovenous fistulas were found in the vascular bed of the diseased limb of 9 of these 13 patients High concentration of oxygen was found in the diseased venous trunks Arteriography helped to locate these trunks, but the authors warn that arteriography may give negative results if, because of location, size, and spasm, the contrast medium cannot reach the fistulas The authors believe that the fistulas were the cause of the relapse Hemodynamic alterations that interfered with the nutrition of the peripheral zones were also present Amputation of the diseased limb is the only treatment from which these patients can derive permanent benefits

Emergency Definitive One Stage Surgery for Intestinal Obstruction W H Ferguson and W W Chase M Ann District of Columbia 26 61-67 (Feb) 1957 [Washington, D C]

The authors began to treat acute intestinal obstruction by a 1-stage definitive operation in 1954 and so far have used this method in 45 patients, including 19 with lesions of the small and 26 with lesions of the large intestine They describe the surgical technique for the small intestine and for the ascending and descending colon, pointing out that surgical decompression of the acutely obstructed colon as well as of the small intestine is a safe and necessary procedure In the hands of a skilled surgeon with modern hospital facilities there should be no need for special equipment or training A through-and-through cotton suture produces an anastomosis that is secure and capable of early function in the small as well as in the large intestine

The following are important aids in management attention to the fluid and electrolyte requirements, preoperative sigmoidoscopic examination, ready availability of a barium enema (no barium should be given by mouth if obstruction is suspected), preoperative introduction of a tube for gastric suction, endotracheal anesthesia, if possible, removal of contaminated tissues and instruments from the operative field, avoidance of intestinal spillage into the peritoneal cavity, changing of gloves and drapes after the anastomosis, introduction of neomycin into the intestinal lumen and the peritoneal cavity, use of through-and-through wire suture if there is doubt about the security of the wound, postoperative dilation of the anal sphincter, giving of neomycin through the gastric tube on the day after the operation, and supportive antibiotic therapy After gas is passed by rectum a regular diet can be started Of the 6 deaths that occurred, 5 were due to medical rather than surgical complications The average stay in the hospital were 10 to 11 days, and normal intestinal function was usually present on the third postoperative day The authors believe that a shorter hospital stay and 1 trip to the operating room are far less demanding in both time and risk than multiple procedures

Surgical Treatment of Nontumorous Temporal Lobe Epilepsy J E Paillas and P Pruvot Presse méd 65 197-199 (Feb 2) 1957 (In French) [Paris]

Of 45 patients with psychomotor epilepsy who were subjected to total temporal lobectomy and followed up postoperatively for from 1 to 7 years, 13 made a complete recovery with complete freedom from attacks At least 75% improvement with a decrease in the number and severity of the seizures occurred in 11 patients The remaining 21 were therapeutic failures in that the number of their seizures remained unchanged or that they were improved by less than 75% Of 37 patients who had personality disorders before the operation 18 were improved This applied particularly to patients with violent compulsions while those with delusions of persecution and with ideas of revenge were not benefited Of 8 patients with impotence or frigidity, 2 showed great improvement The encephalograms of 19 patients revealed disappearance of irritative discharges with tracings within normal limits Nonirritative discharges (delta and theta waves) persisted in the electroencephalograms of 10 patients The abnormal tracings in the preoperative encephalograms remained unchanged in the postoperative encephalograms of 16 patients

Of 14 patients in whom the temporal lobe epilepsy was secondary to fetal dystocia, trauma, or otomastoid infections, 5 made a complete recovery, 7 were improved, and only 2 were therapeutic failures These data suggest that a definitely known causative factor may be a valuable aid in prognosis Of 27 patients with a history of grand mal, 14 made a complete recovery or were improved and 13 were therapeutic failures A history of grand mal does not seem to be a definite contraindication to lobectomy Thirteen of the 45 patients had preoperative neurological signs, such as hemiplegia, hemianopsia, or contralateral sensory disturbances, 8 of these 13 patients were therapeutic failures Lobectomy seems, therefore, to be of doubtful value in patients with neurological signs, and a hemispherectomy may be preferable Of the encephalograms of the 45 patients, those of 37 patients showed unilateral seizure discharges and those of 8 patients bilateral seizure discharges Of these 8 patients, 2 underwent bilateral lobectomy and were therapeutic failures Unilateral lobectomy was performed at the site of the most severe abnormality in the other 6 patients, 2 of whom were improved and 4 of whom were failures These data confirm the unfavorable prognosis of surgical treatment of epilepsy associated with bilateral abnormal encephalograms Of 14 patients in whom pneumoencephalography revealed a cerebral atrophy manifested by a dilation or a unilateral ventricular or localized adhesion of the inferior horn, 5 made a complete recovery, 5 were improved, and 4 were therapeutic failures The radiologic detection of anatomic lesions may be of valuable aid in the operative prognosis

Total frontal lobectomy is associated with a minimum of sequelae and has a favorable effect on the seizures and personality disorders in patients with severe psychomotor epilepsy that is refractory to drug therapy Total frontal lobectomy, however, should be performed only in patients carefully selected with the aid of electroencephalography and radiology and according to the clinical appearance The chances for success are best in patients with epilepsy of dystocic or traumatic origin, with a unilateral circumscribed electroencephalographic focus and with radiologic abnormalities that are characteristic of anatomic lesions or of atrophy limited to the temporal lobe

Acute Ileitis with Ulceration and Perforation Due to Paratyphoid Fever Report of Eighty-five Cases J V Conroy Mil Med 120 79-91 (Feb) 1957 [Washington, D C]

Eighty-five of 203 North Korean prisoners of war with ileal perforation or ulceration due to paratyphoid were operated on The mortality rate was 22% for all patients and none for those who had surgical repair within 2 days of their perforation In most patients a resection of the ileum with end-to-end anastomosis was performed Sixty-seven patients had single perforation and 13 multiple perforations of the ileum and 5 had ulceration without perforation The ileum was dilated, thickened, and covered with a brown exudate and with external evidence of peritonitis All ulcers were transverse and on the antimesenteric border Their depth varied from minimal penetration to perforation The number of ulcers was 1 to 9 in a single resected specimen Acute perforation of the ileum and peritonitis are a much more common complication of paratyphoid, than was previously believed It may be the presenting syndrome of the disease Roentgenograms of the abdomen are a valuable aid in the diagnosis Cultures of the blood, ileal ulcers, and stool should be made in all patients to determine, if an enteric pathogen is the causative agent Operation is the treatment of choice for these patients

Osteoradionecrosis of the Mandible J Gaisford and F Rueckert Plast & Reconstruct Surg 18 436-447 (Dec) 1956 [Baltimore]

Necrosis of the mandible after radiation therapy has been a serious and not infrequent complication ever since this form of treatment was introduced at the turn of the century The authors report their experience in the management of 54 patients with this problem in the past 7 years Most observers believe that necrosis of the mandible is produced by a combination of heavy irradiation, infection, and trauma The mandible, because of its ribbonlike shape, compact composition and presence of but a single nutrient artery on each side, is even more susceptible to the effects of irradiation than the other compact bones in the head Radionecrosis of the mandible may result from x-ray treatment through the jaw aimed at a primary lesion elsewhere in the oral cavity, but usually a cancericidal dose of x-ray for a carcinoma of the mandible itself will result in necrosis of the jaw In the early stages of radionecrosis of the mandible there may be only dental symptoms—hypersensitivity of the teeth, continuous dull toothache, and cavities In the late stages symptoms are severe and constant There is probably no lesion about the head and neck that makes a patient as miserable as this condition There is marked trismus, continuous prolonged pain not responding to the usual narcotics, a foul smelling mouth, and, if there is soft tissue necrosis, there may be a draining orocutaneous fistula Patients with this disease usually have difficulty eating because of the pain and inability to open the jaws As a result they are malnourished, sometimes to the point of starvation

Sixteen of the 54 patients were treated conservatively because their conditions were considered inoperable These all died with uncontrolled tumor Seventeen of the 38 patients in whom resection was performed were found to have necrosis only Twenty of 38 patients subjected to resection died 7 as the result of hemorrhage from the carotid artery, 6 from tumor and necrosis, 5 from other unrelated causes, and 2 from necrosis only When last seen 18 of the patients were alive without tumor The longest survival to date is 7 years, the shortest 3 months Radionecrosis of the mandible and of the adjacent skin is a serious complication, and the authors believe that in most cases it could have been prevented Prompt resection of the necrotic mandible and primary closure of the involved tissues offers the best opportunity for a good result Where primary closure is not possible, reconstruction should be by pedicle flaps

Free skin grafts do not do well when placed over heavily irradiated tissues of the face and neck Jaw reconstruction is not considered necessary for most patients operated on for necrosis of the mandible The surgical risk in this type of case should be negligible Even patients with a few months life expectancy are candidates for surgical treatment because of the palliative results

Cancer of Palate Clinical Study J Fairbanks Barbosa and J B da Silva Netto Rev paulista med 49 191-210 (Sept) 1956 (In Portuguese) [São Paulo, Brazil]

Thirty patients of both sexes with cancer of the palate were observed Most of the patients were between the ages of 50 and 60 years The tumors were squamous cell carcinoma in 25 patients and glandular tumors (mixed tumors, cylindromas, or adenocarcinomas) in five A causal factor found in several patients was the callosity formed by a prosthesis The most frequent forms of squamous cell carcinoma were those marked by superficial, destructive, infiltrating, or vegetating ulceration Glandular tumors appeared as submucous nodules that underwent ulceration and malignant degeneration and caused destruction of the skeletal bones and diffused to nearby structures The diagnosis of the size of glandular tumors was made by roentgenographic examination Malignant glandular tumors of the palate followed a rapid course The prognosis, when the tumors reached the retromolar region, the uvula, or the region of the tonsils or when they perforated the palate and invaded the regions of the nasal fossae, the facial sinuses, or the zygomatic fossa, was poor Tuberculous ulceration and malignant granuloma were the main conditions to be ruled out Carcinoma without involvement of the bones and lymphomas were treated with x-rays Those with involvement of the bones and those resistant to roentgenotherapy were excised Glandular tumors were treated by operation followed by roentgenotherapy In the cases reported most of the patients complained of rapid loss of weight Malignant tumors diffused to the alveolar bones in 8 cases, to the tonsillar region in 8, to the nasal fossae and facial sinuses in 2, and to the pharynx in 1 There was no propagation of the tumor in 11 cases Metastases, either unilateral or bilateral, in the cervical lymph nodes occurred in 14 patients Resection of the metastatic lymph nodes was performed in 5 patients Neoplastic nodes were found on histological examination in the resected material of 4 of the 5 patients No conclusions were drawn by the authors because the follow-up period was only 2½ years

The Treatment of Diabetic Arteritis of the Lower Limbs M M Plauchu J méd Lyon 38 113-124 (Feb 5) 1957 (In French) [Lyon, France]

Arteritis is 11 times more frequent in diabetics than in normal persons The frequency is high among patients who have had diabetes for more than 5 years The author found that of a group of 211 diabetic patients 45 had arteritis Arteritis occurred in 10% of those who had had diabetes for less than 5 years, in 10% of those who had had diabetes for 5 to 15 years, and in 40% of those who had had diabetes for more than 15 years No direct relationship between the frequency of arteritis and the fact that the patients had been treated with insulin was found Obesity and superalimentation should be considered only as predisposing factors Of 45 patients with arteritis, 17 were obese and 27 had retinal lesions Latent diabetic arteritis was the most frequent form observed It was located in the upper limbs only in 2 patients Good control of the diabetes, use of iodides, and a diet poor in lipids are advised by the author for the treatment of latent diabetic arteritis Diabetic arteritis not complicated by gangrene may persist for several years Intermittent claudication was the first symptom in 11 of 19 patients with arteritis The authors advise control of the glycosuria and maintenance of a normal blood sugar level Intra-arterial and intrathecal injections are preferred to treatment with vasodilators Physiotherapy should be considered only as a secondary type of treatment Periarterial and lumbar sympathectomy are of some help Seventeen of the 45 patients with arteritis had gangrene Diabetic coma in patients with gangrene is rare, it occurred in only 1 of the 17 patients Lowering the blood sugar level and intra-arterial injections of procaine, heparin, and penicillin constitute the best treatment for patients with gangrene Amputation performed at a sufficiently high point is still the only treatment for patients with massive gangrene In such patients the prognosis is poor

The Plastic Replacement of Severed Flexor Tendons of the Fingers T L Sarkin Brit J Surg 44 232-240 (Nov) 1956 [Bristol, England]

The occurrence of an injury involving the flexor tendons of the finger within the digital theca is a calamity At best the treatment is prolonged and complicated, and many patients never recover a functioning finger The technique that is now generally accepted as giving the most consistently satisfactory results is the transplantation, with a free tendon-graft, of the cut flexor digitorum profundus tendon from the palm of the hand to the distal phalanx, and the complete removal of the flexor digitorum sublimis tendon in this area Free grafting of the profundus tendon requires special skill, experience, and great care Even experts occasionally fail to obtain satisfactory results Other disadvantages of this method are the length of time required for rehabilitation during which supervision and physiotherapy, together with the cooperation and willingness of the patient, are necessary and the fact that the effective treatment of a divided profundus tendon requires the presence of a normally functioning sublimis unit The key to success in tendon repair lies to a large extent in the total avoidance of adhesions around the tendon A technique is described and illustrated in detail whereby severed flexor tendons in the digital theca are replaced by a double length of adequate strength nylon covered by polythene tubing, which is inserted as a functioning unit between the distal phalanx, through which it is passed, and a profundus tendon at the wrist, to which it is firmly sutured, passing through the tendon-sheath en route from the finger to the wrist

The possible disadvantages and difficulties of the technique are discussed, namely the questions of the strength of the plastic and of the junctions between it and the phalanx distally and the tendon proximally and its inertness in the body The evaluation of the late clinical results will require more time The principle of artificial tendons might eventually be extended to the field of tendon transplantations and the rehabilitation of the paralyzed If artificial tendons can function along anatomic pathways, there appears to be no reason why they should not function along artificial pathways Often a tendon transplantation is not practicable due to the anatomic lack of a suitable nearby tendon If this limitation is removed, there is no theoretical reason why a suitable muscle far removed from the paralyzed area should not provide the motor power to that area via a long artificial tendon

Treatment of Angiomas R W O'Brien Plast & Reconstruct Surg 18 448-459 (Dec) 1956 [Baltimore]

The multiplicity of names applied to angiomas has led to confusion, but they may be grouped into 2 broad categories, namely the capillary and the cavernous Capillary hemangiomas include the port-wine stain or nevus flammeus and the strawberry birthmark or hemangioma simplex The cavernous angiomas are soft compressible tumors consisting of large thin-walled sinuses with little intervening stroma They may produce pronounced enlargement of the cheek, nose, ears, lips, and other facial structures and may interfere seriously with function They often produce blue discoloration of the overlying skin, indicating a predominant venous component Phleboliths often develop within them Cirsoid aneurysms are related closely to cavernous angiomas and in fact may be cavernous angiomas with single or multiple arteriovenous fistulas Spontaneous regression occurs frequently but not invariably in hemangioma simplex, but spontaneous regression is not observed in the port-wine and cavernous angiomas The relative ease with which these lesions can be treated in an early stage and the great difficulty of restoring normal or near normal appearance, even after spontaneous regression, when involvement is extensive make it necessary to treat them when they are still small Accordingly, it appears to be highly illogical to adopt an expectant attitude, as some have proposed In addition to progressive growth, these lesions may ulcerate, become infected, and give rise to profuse, and at times fatal, hemorrhage

Except when growth, pressure, or hemorrhage is producing imminent danger, the treatment of these lesions is not an emergency Therefore, it behooves the physician or surgeon never to use a method of treatment that may endanger life or produce greater disfigurement or dysfunction than is likely to result from nontreatment Surgical excision of both capillary and cavernous hemangiomas is being resorted to more and more, as it is safer and produces fewer complications than do other methods of treatment, and it gives satisfactory cosmetic results When irradiation is used, extreme care must be taken in evaluating the dosage Cavernous hemangiomas whose situation and extent render excision inadvisable are best treated by means of injection of sclerosing solutions, by electrocoagulation or by a combination of these methods

Biliary Ileus R Mosimann Helvet chir acta 23 496-512 (Dec) 1956 (In French) [Basel, Switzerland]

Thirteen of more than 200 patients with intestinal obstruction and 450 with gallstones were found at operation to have biliary ileus Three of the 13 died, and 1 required a 2nd operation because of duodenal stenosis Spasm, parietal edema, and localized enteritis were frequent symptoms The latter caused necrosis and intestinal perforation in 1 patient Ten patients had pain in the right hypochondrium Visible calculus in the terminal part of the dilated intestine was the most reliable roentgenologic finding Presence of gas or of some contrast medium in the bile ducts was another significant roentgenologic finding A median incision below and above the navel permitted exploration of the intestine in its entire length Transverse or longitudinal enterotomy was performed and transverse absorbable surgical sutures were placed in 3 layers continuously after clamping of the intestine Palpation of the gallbladder often fails to reveal the calculus because of its close adherence to the liver Great caution is required in making the dissection in order to avoid perforating the intestine or the gallbladder This accident makes cholecystectomy inevitable and greatly aggravates the situation Some biliary-intestinal fistulas close spontaneously and do not cause any more trouble In 1 patient such a fistula caused an intestinal stenosis Laparotomy showed in this patient that a band of adhesions had constricted the lumen of the duodenum Except for one patient who was observed 2 years after the operation, the authors were unable to make roentgenologic examinations to find out what had happened to the fistulas Biliary-intestinal fistulas should be left intact during the 1st operation for biliary ileus and repaired later An exception to this rule should be made only in case of duodenal stenosis or in presence of clinically observable cholangitis

Traumatic Pneumopericardium Case F Rosa and H Coardeza Arch urug med 49 80-90 (July-Aug-Sept) 1956 (In Spanish) [Montevideo, Uruguay]

Traumatic pneumopericardium is rare When pneumopericardium is due to associated lesions of intrathoracic and intraperitoneal structures, the diagnosis is difficult and the prognosis is serious The subject of this report was a child 4-years-old who was brought to the hospital immediately after he had suffered a wound in the chest by a firearm The patient was vomiting food and blood at repeated intervals, but not constantly The clinical symptoms were those of perforation of an abdominal viscus The patient had no shock The roentgenogram of the chest and a lateral teleroentgenogram showed a pneumopericardium as a transparent band of air within the cardiac shadow The operation was done immediately with the patient under general anesthesia It showed wounds in (1) the diaphragm (2) the left posterior lobe of the liver, and (3) the lesser curvature of the stomach The operation consisted of suture of wounds, leaving a peritoneal drain The postoperative course was uneventful, there was rapid recovery without sequels Clinical, roentgen and electrocardiographic follow-up showed permanent cure of the patient

Hemolytic Transfusion Reaction with Fatal Outcome Due to Rare Blood Type Antibody (Anti C) B Barfod and G Munk-Andersen Ugesk læger 119 37-40 (Jan 10) 1957 (In Danish) [Copenhagen]

The fatal hemolytic transfusion reaction reported was due to an Rh undertype antibody, anti-C The presence of another rare blood type antibody of immune character, anti-Jk^a, was demonstrated 1 week after the transfusion The authors discuss performance of compatibility tests that can establish antibodies outside of the ABO system, especially in the case of recipients who have previously been exposed to an immunization either by blood transfusion or by pregnancy As increasing application of transfusions will bring about more frequent immunization of the patients, with consequent increasing risk of transfusion complications, blood transfusions should be prescribed only on well-considered indications

NEUROLOGY & PSYCHIATRY

The Outcome of Patients with Herpes Zoster J M de Moragas and R R Kierland A M A Arch Dermat 75 193-196 (Feb) 1957 [Chicago]

Generally herpes zoster resolves without complication, but in some patients it produces complications or sequelae that may incapacitate the patient The most important among these is postherpetic neuralgia The authors analyze some of the factors that determine the severity of the disease They attempt to outline its natural course and to provide a "base line' useful in determining the results of treatment The records of 916 patients seen at the Mayo Clinic between 1935 and 1949, inclusive, with the diagnosis of herpes zoster or postherpetic neuralgia were reviewed Sex distribution was essentially even Study of the patients was undertaken by groups divided by ages in decades Duration of the postherpetic neuralgia was used as an index of the severity of the process It was found that the incidence of herpes zoster increased with age, from 24 in patients in the age group under 20 years to 270 in patients in their 60's The group aged 70 years or more included 160 patients, absolutely a smaller number but actually larger, considering the relatively smaller percentage of population in this age group

Postherpetic neuralgia likewise showed a relationship to the ages of the patients As the age increased, the number of patients without pain diminished from 83 3% in the age group under 20 years to 8 7% in the age group of 70 years or more Simultaneously, the duration and severity of the postherpetic neuralgia increased Trigeminal location of the herpes zoster was observed in 149 patients (16 3% of the total) The postherpetic neuralgia was of longer duration in this group than in the entire series Also this group was more prone to have severe complications during the acute phase of the disease Enucleation of the eye was done in 2 patients, owing to perforation of the cornea and to absolute glaucoma The different age groups received the same type of treatment during the acute phase of the disease Acetylsalicylic acid, autohemotherapy, and roentgenotherapy were the more widely used To relieve postherpetic neuralgia, roentgenotherapy, cobra venom, posterior pituitary extract, Protamide (a proteolytic enzyme preparation), and vitamin B_1 and B_{12} were given to most of the patients Infiltration of procaine hydrochloride, which was performed in 14 patients, helped 2 Infiltration of alcohol, which was performed in 23, also helped 2 Avulsion of the nerve, which was performed in 6 was of no value Rhizotomy was effective in 3 of 8 patients Treatment of postherpetic neuralgia did not seem to change the slow tendency of the neuralgia to improve with time, but in some instances, fortunately very seldom, the severity of pain was stationary or even progressive Age and localization (trigeminal) seemed to be the decisive factor in the prognosis of herpes zoster

Electroencephalographic Study of a Few Cases of Hepatic Coma R Cloche Presse méd 65 135-137 (Jan 23) 1957 (In French) [Paris]

Electroencephalographic examinations were made in 14 patients with neuropsychiatric symptoms associated with severe hepatic insufficiency Anomalies of a characteristic, ample, and spiking type, presenting a positive component, were observed in 6 patients who were examined during precoma and coma The tracings varied with the degree of unconsciousness An evaluation of the blood ammonia level made during coma in 2 patients showed it to be high No relation was found between this level and the intensity of the coma

Treatment of Mental Illness The Use and Misuse of Sedation and the Seclusion Room H A Wilmer California Med 86 93-98 (Feb) 1957 [San Francisco]

A series of 939 patients admitted to the locked receiving ward in the psychiatric service of the U S Naval Hospital, Oakland, Calif, over a 10-month period, many of them psychotic and in an acute initial episode, was treated with group therapy, which more appropriately should be called a therapeutic community The locked ward contained 34 beds in a single room The concept of the therapeutic community involves free communication among patients, between patients and staff, and among members of the staff The staff was told in the beginning of this experiment that the use of the quiet room would be discontinued and that sleeping pills were to be given only in unusual circumstances A formal sick call was held each morning, followed by a ward group meeting lasting about 45 minutes, at which all patients and staff—nurses and corpsmen—were expected to be present Only 2 of the 939 patients refused to attend the meetings Both were severely paranoid schizophrenic patients who were overwhelmed by fear Immediately after the group meeting, the staff met separately to discuss the meeting and ward and staff problems While the staff was holding its meeting, the patients gathered in a spontaneous group on the ward At first the staff doubted whether the ward could be operated without the use of quiet rooms, restraint, and parenteral sedation Within 2 or 3 months it was obvious that the plan would work and that the best and most humane qualities in staff and patients were brought to the fore

The routines of the ward were group-oriented, but group therapy as such played only a small part Group membership was constantly changing, with an average of 3 patients coming and going every day On the entry of severely sick, new patients, a spontaneous psychodrama was performed As many as 5 or 10 patients were admitted at one time, some in mechanical restraint and many of them after having spent days or weeks in seclusion rooms in other hospitals Only about 8% of the first 250 patients admitted received chlorpromazine and reserpine After 4 months, when it became evident that the social and therapeutic experience of the ward milieu was effective and that its efficacy did not depend on medication, the newer drugs were evaluated At the end of the 10 months 27 6% of the patients were receiving 1 of these drugs They were considered to be of particular help in treating the more aggressive, hyperactive psychotic patients and those with delirium tremens The decline in the use of the quiet room and sedation on the receiving ward, as well as an increase in use of the tranquilizing drugs, coincided with a decrease in use of electroshock and a discontinuance of the use of insulin coma therapy in the hospital Patients who did not require a locked ward were quickly transferred to the open receiving ward which was established 5 months after this program began It was possible to greatly diminish the quantity of sleep-inducing drugs and practically to eliminate the parenteral administration of barbiturates Restraints were never used To be dealt with in this atmosphere of candor and relative freedom seemed to evoke a responsive attitude in the patient, and many of them benefited from it

Dizziness Attacks and Continuous Dizziness in the Aged E J Orma and M Koskenoja Geriatrics 12 92-100 (Feb) 1957 [Minneapolis]

This is a 2nd report on dizziness in a group of patients over 64 years of age, who did not represent a random sample of old people with dizziness because the subjects were solicited through newspaper advertising and included a large number of patients with more severe forms of dizziness than would be the case in a random sample Physical, neurological, otorhinolaryngologic, and ophthalmological examinations, laboratory tests, and roentgenographic studies were made The authors discussed in an earlier report the postural type of disturbance in equilibrium, which is the most common type of dizziness observed in the aged A table listing the type of attack of dizziness in the 45 patients reviewed here shows that the attacks were of central neurological origin in about half of the patients, that is, in 12 they were definitely so and in 10 they were probably of this origin An attack of dizziness was regarded as neurological in origin if other clear neurological symptoms had been associated with it and other causes, especially the otogenous, could be excluded In the remaining 23 patients, the attacks of dizziness were connected with Ménière's disease, chronic otitis media complicated by labyrinthitis, a labyrinthine vascular accident, angina pectoris, cardiac arrhythmias, laryngeal vertigo, infections, poisoning, agoraphobia, vomiting, and head injury

The authors define continuous dizziness as a continuous disturbance in equilibrium independent of movement or position This symptom was observed in only 8 of 112 elderly patients with dizziness Most of the patients of this group were in poor physical condition Many had severe ataxia and tremors and poor mental activity Apparently such continuous dizziness occurs in patients with extensive, diffuse brain lesions, either degenerative or arteriosclerotic

The Response of Normal Men to Lysergic Acid Derivatives (Di- and Meno Ethyl Amides) Correlation of Personality and Drug Reactions J M von Felsinger, L Lasagna and H K Beecher J Clin & Exper Psychopath 17 414-428 (Oct-Dec) 1956 [New York]

Lysergic acid diethylamide was given to 10 healthy men and lysergic acid ethylamide to 9 similar persons after psychological interviews and Rorschach tests in an attempt to increase understanding of the psychological and physiological factors involved in psychotic states by reproducing such states with the aid of these drugs in these volunteers Interviews and Rorschach tests were repeated during the height of the reaction of the volunteers to lysergic acid diethylamide Total doses of lysergic acid diethylamide varied from 39 to 86 mcg, most persons receiving 1 mcg per kilogram of body weight The drug was given orally either in the fasting state or after a light breakfast The total dose of lysergic acid ethylamide was 0 25 mg in 3 persons and 0 5 mg in 6 persons The drug was given subcutaneously Both the drugs were administered as unknowns

The following observations were made in the men who received lysergic acid diethylamide changes in vital signs were of slight moment, giddiness, tremulousness, and paresthesias were frequent, mood changes included, commonly, tension or anxiety and desire to laugh without cause, less frequently euphoria and erotic sensations were encountered, thought and speech processes were slowed down and efficiency impaired, and perceptual changes or visual illusions were produced in half the persons After taking the drug 7 of the 10 volunteers showed distinctive changes in the Rorschach test taking the form of an exaggerated caricature of the predrugged state in which weaknesses of ego function were intensified The degree of change in Rorschach findings and the amount of reaction to the drug were correlated positively with personality disturbances or maladjustment Observations in the men who were given lysergic acid ethylamide were as follows Transient hypertension, tachycardia, tachypnea suggestive of epinephrine release, paresthesias, dizziness, and nausea were frequent Mental changes were predominantly experienced as dulling of the senses, confusion, shakiness, and apprehension Four of the 9 volunteers became mildly hostile and paranoid One other experienced acute panic As with lysergic acid diethylamide, the degree of drug reaction was positively correlated with personal maladjustment

The changes produced by these drugs were not striking conversions of normal to psychotic but rather consistent expansive exaggerations of the predrugged personality in which structural weaknesses and immature factors were magnified In some persons whose personalities are already characterized by pathological signs, such a process may produce a "psychotic" picture The process itself is better viewed as a release of existing tendencies rather than as a creation of new elements Problems of control and design are especially difficult in drug experimentation, not to speak of experimental psychiatry, and the ideal is rarely achieved The use of persons as free as possible of bias, suggestion, and vested interest is essential The use as subjects of members of the laboratory staff, physicians, and nurses may lead to erroneous conclusions

PEDIATRICS

Investigations on Immunity After Vaccination Against Diphtheria and Status of Antidiphtherial Vaccination in Amsterdam Children A L Noordam and A M Schrick Nederl tijdschr geneesk **101** 141-144 (Jan 19) 1957 (In Dutch) [Haarlem, Netherlands]

Immunization against diphtheria has been facilitated since diphtheria toxoid has been combined with aluminum phosphate Investigations carried out on Amsterdam children in 1955 showed that, of the 4-year-old children who entered nursery schools (which are attended by 85% of all children), 57.5% had been immunized against diphtheria, 35 2% had been immunized during the 1st year of life and 22 3% between the 1st and 4th years Of the 6-year-old children, 95% had been immunized against diphtheria Of the 4-year-old children who had had their first 2 injections with alum precipitated toxoid about 4 years previously but who had not had a booster injection since then, 92% had a negative Schick reaction, whereas, of those who had not been vaccinated at all, 20% showed a negative Schick reaction, and all those who had received a booster injection had negative Schick reactions Of the children of primary-school age (6 to 12 years of age), 98% had a negative Schick test About 25% of the antidiphtherial vaccinations in children under 4 years were carried out by the family physicians and 75% by health officers In 1955 health officials immunized about 45% of all babies against diphtheria (and whooping cough), and another 10% of the babies were immunized by their family physicians The authors believe that the propaganda for the immunization of infants against diphtheria should be increased They also recommend that 2 booster injections should be given, the 1st one when the children are between 4 and 5 and the 2nd when they are between 7 and 8 years of age

Clinical and Statistical Correlations in 71 Patients with Tuberculous Meningitis Treated in the Pediatric Clinic of the "Ospedale Maggiore" of Lodi F Brocca and G Sacchetti Riv clin pediat 58 202-212 (Aug) 1956 (In Italian) [Florence, Italy]

The authors report on 71 children with tuberculous meningitis treated between 1947 and 1956 A 1st group of 12 children was treated with streptomycin combined with a sulfone Each child received from 21 60 to 43 35 Gm of streptomycin intramuscularly and from 1 42 to 2 20 Gm intrathecally Three of the 6 children who died were in poor condition on admission Sequelae were not observed, and streptomycin had no toxic effect on the children who recovered The period of hospitalization for the patients who died was from 4 days to 1 month, and for those who recovered it averaged 5½ months A 2nd group of 38 children was treated with streptomycin combined with aminosalicylic acid (PAS) and thiosemicarbazone A total dose of from 15 3 to 64 2 Gm of streptomycin was injected in each child intramuscularly, and from 0 94 to 4 45 Gm was given intrathecally PAS was administered in a dose of from 3 to 6 Gm per day Of 20 children who died 10 had come to the hospital in poor condition The children who recovered were hospitalized for an average period of 5½ months Relapses occurred in 10 children

A 3rd group of 21 children was treated with isoniazid combined with streptomycin Streptomycin was given in a dose of 20 mg per kilogram of body weight daily for 45 days and then at an interval of 3 or 4 days until a total dose of from 40 to 50 Gm was reached Isoniazid was given in a dose of from 10 to 20 mg per kilogram of body weight until the spinal fluid findings returned to normal and then from 1 to 2 mg per kilogram of body weight as long as the condition of the patient required Of 4 children who died, 3 were in poor condition on admission Four and a half months was the average period of hospitalization for the children in this group who recovered Superimposed meningitis or relapses did not occur Sequelae occurred in 2 children The authors believe that the combination of streptomycin and isoniazid provided the best treatment Early diagnosis and treatment are necessary for the best results

Absorption of Iron from Vegetables in Infants Value of Homogenized Preparations A Lambrechts, Y Feuillen and C Hubin Rev med Liege 12 63-65 (Feb 1) 1957 (In French) [Liège, France]

Twenty-two determinations of iron absorption from the diet were carried out in infants between the ages of 5 and 12 months They were given milk that was diluted to one-third and to which sucrose and flour was added They also received soup that was prepared from (1) fresh spinach, boiled and strained (purée), (2) homogenized canned spinach, and (3) fresh spinach, boiled, strained, and treated in a mixer The iron ingested with the combination of milk and soup amounted to 1 or 2 mg daily The total iron was estimated by the o-phenanthrolin colorimetric method after mineralization Results showed that the absorption of iron was definitely better when the infants were fed soup made from homogenized canned spinach than when they were fed that made from boiled and strained fresh spinach The absorption ratio was 12 9% of the ingested amount when fresh spinach treated in the common culinary manner was fed and 32 5% when canned homogenized spinach was fed The absorption of iron from soup made from homogenized canned spinach was almost identical with that from soup made from fresh boiled spinach treated in a mixer Homogenized vegetables constitute an alimentary supply that is appealing to the infant The preparation of vegetables is an important factor that should be considered with regard to iron absorption

THERAPEUTICS

Daptazole and Megimide in Treatment of Acute Barbiturate Intoxications K Madsen Tidsskr norske lægefor 77 60-63 (Jan 15) 1957 (In Norwegian) [Oslo]

Daptazole and Megimide combined were given to 14 patients in the treatment of barbiturate intoxication The most notable effect was increased reflex activity and improved respiration, regarded as certain signs of reduction of the depth of intoxication, so that the patients came into a safe state The patients were closely observed during treatment and awakening The duration of the coma did not seem to be shortened nor did the barbiturates seem to be eliminated more rapidly The side-effects were usually moderate In 1 case paranoid psychosis recurred The motor unrest was, as a rule, easily controlled The agents are regarded as valuable in the treatment of deep intoxications, but they are not to be considered as specific barbiturate antidotes and do not in any way make the usual general therapy superfluous

Diacetylcolchicine in Antiblastic Therapy W Paolino, G Pierri and L Resegotti Minerva med 48 1-10 (Jan 6) 1957 (In Italian) [Turin, Italy]

The authors report the results obtained in 78 patients with different types of neoplasm treated with diacetylcolchicine The drug given intravenously does not cause local vascular reaction and does not depress the general condition of the patient Side-effects caused by tropism of the drug on particular tissues were noticed in some patients, mainly, side-effects appeared in patients with forms of neoplasm that were not much benefited from the administration of the drug Protection of the normal tissues was obtained by giving a small dose of corticotropin intravenously, prednisone by mouth, or adenine intramuscularly The initial dose of diacetylcolchicine was 7 to 10 mg This dose was continued, decreased, or given at longer intervals depending on the form of neoplasm and the occurrence of side-effects The leukocyte count returns to normal after an interruption of treatment for a few days An initial leukocyte count of 3,000 to 4,000 per cubic millimeter was not considered a contraindication to treatment with this drug Daily treatment with large doses of the drug was never continued for more than 10 to 15 days, except in patients with chronic granulocytic leukemia Treatment with a smaller dose (5 mg) given at intervals of one or more days was never continued for more than 20 to 30 days Good renal function is a prerequisite for this treatment Results were excellent and lasting in patients with chronic granulocytic leukemia, excellent but less lasting in patients with reticulosarcoma, good and, in some cases, excellent in patients with malignant lymphogranuloma, good in some patients with lymphosarcoma or pulmonary metastasis due to carcinoma of the breast, and fair in some patients with primitive carcinoma of the lung, in 1 with melanosarcoma, and in 1 with reticuloendotheliosis The drug had no effect on a patient with fibrosarcoma Subjective improvement occurred in 2 patients with carcinoma of the ovary The remission can be maintained by giving a small dose of x-ray and in patients with malignant lymphogranuloma by treating them subsequently with methenamine

The Mass Treatment of Tapeworm with Mepacrine J A McKinnon East African M J 34 15-18 (Jan) 1957 [Nairobi, Kenya Colony, Africa]

During a routine hygiene inspection in the works camp at Marigat in the Baringo district of Kenya, it was noted that many of the stools contained tapeworm segments The investigation and treatment of this Taenia infestation provided an opportunity for the trial of the efficacy and safety of quinacrine (mepacrine) in mass treatment The scheme adopted was designed to provide a measure of laboratory control while the treatment was simplified as would be necessary in mass treatment The population of the camp was divided into groups of 40 persons, and a timetable was drawn up with 1 day devoted to investigation and treatment of each group and, 3 days later, a day for follow-up investigation of that group On the treatment day all men in a group were given a dose of 480 grains (31 7 Gm) of magnesium sulfate on an empty stomach All stool specimens were examined Those that did not contain visible tapeworm segments were examined microscopically for tapeworm ova After that the 494 men (of a total of 1,120 men) whose stools had contained either visible segments (444) or ova (50) were given 0 8 Gm of quinacrine by mouth in 4 equally divided doses at 5-minute intervals, with sips of an antacid mixture to prevent nausea and vomiting between doses One hour after the last dose of quinacrine, 960 grains (63 4 Gm) of magnesium sulfate was given by mouth

Investigations on the 4th day after treatment showed that 42 of the 494 men still had visible segments in their stools and an additional 70 had tapeworm ova on microscopic examination This initial failure rate of 22 67% was higher than expected New tests were made before these men were treated again, and it was found that only 13 had visible segments in their stools and 48 others had tapeworm ova, a total of 61 These patients were re-treated, after which only one man had tapeworm segments and an additional 7 had ova, i e , 8 out of the original 494 treated

Three months after the original treatment the 200 men remaining in the camp from the original 494 men treated were examined Of 170 men who had received only one course of quinacrine, the stools of 4 contained segments and 12 contained ova Of the 30 men who had received 2 courses of quinacrine the stools of 2 contained ova The general failure rate in the 200 was 9% This failure rate and the virtual absence of adverse effects indicate that the use of quinacrine for mass treatment of *taeniasis*, with suitable adjustment of dosage for children and the chronic sick is safe and relatively effective and that by this method it should be possible to reduce tapeworm infestation in a community to negligible proportions

The Importance of the Intradermal Reaction to Penicillin as an Index of Sensitization D Betetto and M Graziani Gior veneto sc med 11 149 159 (May-June) 1956 (In Italian) [Venice, Italy]

The cutaneous reaction was studied in 150 patients who were being treated with penicillin The intra dermal test was made with a solution containing 1,000 units of crystalline penicillin G per cubic centimeter An isotonic sodium chloride solution was used as a solvent The control test was made with an injection of the saline solution alone Twenty patients (13%) were found to be sensitive to penicillin An erythematous zone appeared a few minutes after the intradermal injection in 14 patients, the same plus intense itching occurred in 2 patients, erythema and a positive Prausnitz-Kustner reaction occurred in 4 patients All 20 patients had been previously treated with penicillin, 10 had had a disease considered sensitizing to penicillin, 5 had had bronchial asthma, 3 tonsillitis, 1 trichophytosis, and 1 tuberculous pleurisy Negative results to the intradermal test occurred in the remaining 130 patients, 68 of whom had never been treated with penicillin Seventeen of the 130 had in the past been affected with a disease considered sensitizing to penicillin The authors believe that intradermal tests should be given before subjecting patients to treatment with antibiotics

Myleran in Chronic Myeloid Leukemia Advantage of Systematic Maintenance Treatment J Closon and M Content Rev belge path et med exper 25 413-430 (Nov) 1956 (In French) [Brussels]

Six patients with chronic myeloid leukemia were treated with busulfan (Myleran) Therapy consisted in giving large initial doses (2 to 8 mg daily) for 10 to 22 weeks and maintenance doses of 2 to 6 mg per week for 12 to 16 months The whole treatment was extended over a period from 14 to 21 months with a total dosis of 660 to 950 mg of busulfan Excellent remissions up to 2 years were obtained in 3 patients The antimitotic agent was well tolerated by 5 patients Untoward reactions due to idiosyncrasy and to an acute fatal evolutive phase of the disease occurred in one The chief advantage of busulfan is its efficacy when radiotherapy has been of limited or no value Maintenance therapy requires monthly blood cell counts The advantage of prolonged treatment with busulfan is limited by a progressive resistance of the leukemic cells to the drug In this case, combined treatment with busulfan and x-rays should be given The treatment with busulfan seems to be more effective than x-ray therapy It is, therefore, the treatment of choice in chronic granulocytic leukemia

PATHOLOGY

Investigation of Non Ulcer Dyspepsia by Gastric Biopsy A W Williams, F Edwards, T H C Lewis and N F Coghill Brit M J 1 372-377 (Feb 16) 1957 [London]

The authors consider dyspepsia a condition in which abdominal or thoracic symptoms other than dysphagia occur in relation to eating Nonulcer dyspepsia implies the occurrence of such symptoms when no ulcer can be found in the esophagus, stomach, or duodenum not previously operated on A group of 775 patients with dyspepsia was studied by means of a barium-meal The examination was repeated and gastroscopy was performed when there was doubt about the results Of this group, 459 (59 2%) were men and 316 (40 8%) women Investigation revealed a likely organic cause for the dyspepsia in 307 (39 6%) duodenal ulcer in 195, gastric ulcer in 79, gastric and duodenal ulcers in 7, hiatal hernia in 16, esophageal reflux in 3, gastric carcinoma in 3, cardiospasm in 2, esophageal ulcer in 1, and volvulus of the stomach with eventration of the left side of the diaphragm in 1 Investigating gastritis as a cause of dyspepsia, biopsies of the gastric mucosa were obtained in 200 patients with nonulcer dyspepsia The authors consider several categories of mucosal lesions, and an analysis of the results when multiple specimens were obtained showed agreement between them in 80 to 90% of the cases There was evidence that the greater the number of samples examined the greater the chance of finding atrophic gastritis The mucosa was normal in 45% of these 200 patients There were mild changes—mainly those of chronic gastritis—in 36% (miscellaneous group) and more severe in 4 5% (superficial gastritis) A diagnosis of chronic atrophic gastritis was made in 14 5% of the patients There were no notable differences in the incidence of gastritis between the sexes, but the atrophic type became more frequent as age advanced The milder changes occurred about as frequently at all ages Hydrochloric acid production on histamine stimulation fell away as severity of gastritis increased

Attempt at Anatomopathological Classification of Chronic Pancreatitis Comparison with the Pancreatographic Aspects H Leger and L Leger Presse med 64 2168-2172 (Dec 25) 1956 (In French) [Paris]

Many difficulties are encountered in attempting to define the pathological processes responsible for the lesions found in biopsy specimens obtained from patients with chronic pancreatitis Careful study, however, has shown that, in spite of the varied and often complex changes evident in the slides, a search for the dominant histopathological element will supply information suggesting the cause of the condition and indicating the methods that should be used in attempting to correct it Thus the predominance of ductal dilatation accompanied by gross sclerosis, but with little derangement of the lobules and few changes in the acini, suggests obstruction of the excretory passages and indicates a need for a procedure providing drainage or retrograde decompression Again, the special picture presented by paraneoplastic pancreatitis, with or without ductal dilatation, should lead to a search for the tumor and to wide excision Finally, the topographic distribution of the sclerosis that develops in the course of portal hypertension, chronic endarteritis, and various other conditions produces pictures that are distinctive enough to be easily recognizable, but, even in these cases, such factors as the primary acinic changes, the phenomena of duodenal congestion, spasm of the sphincter of Oddi, and abrupt changes of pressure in the ducts may favor ductal disturbances and distention from above that are also perfectly apparent in the histological specimens and that may be susceptible of improvement by a drainage or bypassing procedure

A distinctive picture generally recognizable in biopsy specimens taken from peripheral zones, but not including the important excretory ducts close to the pancreatic duct, can be drawn up for each of the principal types of chronic pancreatitis Paraneoplastic pancreatitis for instance, is accompanied by many changes, but those that seem to be the most characteristic are the special distribution of the fibrosis that develops between the acini, forcing them more or less widely apart, and the increase in the volume of the acini with cellular hyperplasia or else their tendency to atrophy and destruction These changes are apparently linked as much to the so called desmoplastic properties of the neighboring tumor as to the inflammatory and degenerative phenomena produced by the rupture of the acini, which undergo progressive distention while retaining a certain secretory activity Pancreatography in patients with cancer reflects quite faithfully the dilatation of the principal duct, which is always pronounced, while little change is seen in the smaller ducts—facts that have been noted histologically by others

The term ductal pancreatitis with fibrosis and ectasia is reserved by the authors for the changes produced, principally in the excretory passages, as a result of distention, stasis, or obstruction of any kind other than cancerous The condition referred to as pancreatitis due to obstruction, in which an obstruction to the outflow of pancreatic juice is recognized, sometimes exists in the pure state, but it may also be associated with pancreatitis of a different type, either primary or accompanying hepatic cirrhosis Relapsing pancreatitis is characterized by clearly enlarged interlobular spaces, sometimes presenting a fairly compact fibrous appearance and sometimes loose and edematous with many dilated and congested vessels Dilatation of the excretory ducts and a certain amount of peripheral fibrosis are also found in many cases, but these changes are always subordinate to those produced by vasomotor disturbances Finally, the earliest changes in primary fibrous pancreatitis are those affecting the differentiated acinic cells The fibrosis, which appears as a reparative process only after cellular degeneration, develops at the periphery of the lobules in contact with the cells that are most affected Examples of these changes may be found in pancreatitis accompanying alcoholic cirrhosis of the liver, pigmentary cirrhosis, and anemic syndromes and in chronic fibrous pancreatitis of arterial origin

So Called Xanthomatous Biliary Cirrhosis and Chronic Pseudoxanthomatous Pericholangitis G Hartmann Frankfurt Ztschr Path 68 55-63 (No 1) 1957 (In German) [Munich, Germany]

Xanthomatous biliary cirrhosis is characterized by (1) mechanical (obstructive) jaundice that persists for years, fluctuates only slightly in intensity, and is accompanied and often preceded by pruritus, (2) hepatosplenomegaly with induration, in which the liver surface is at first smooth and later hob-nailed and in which ascites appears either late or not at all, (3) cutaneous xanthomas on the face (particularly the lids), the upper extremities (especially elbows and fingers), the distal parts of the lower extremities, and occasionally also in the axillary and gluteal folds, and (4) severe hyperlipoidemia, in which the cholesterol value is from 4 to 10 times higher and the lecithin value from 4 to 8 times higher than the normal The serum remains transparent because of the rather low neutral-fat content The disease usually ends in death from hepatic insufficiency or from hemorrhage from ruptured esophageal varices It occurs chiefly in women The pathological changes in the liver were thoroughly investigated by MacMahon who characterized the lesion as a pericholangiolitic biliary cirrhosis

The author describes the history of a 50-year-old woman who had had pruritus for several years and who was hospitalized because of the recent development of jaundice Her urine had become dark brown, and the stools were very light Her liver and spleen were enlarged and indurated Because the jaundice suggested obstruction an exploratory laparotomy was performed This revealed a normal gallbladder and no obstruction in the extrahepatic bile ducts Conservative therapy produced no improvement Later the patient had an attack of herpes zoster and hemorrhoids Because the jaundice continued, the patient was again subjected to laparotomy, but the gallbladder and large bile ducts again proved normal A wide cholecystogastrostomy was made A biopsy specimen was taken from the edge of the liver Studies revealed that the pathological substrate of the chronic jaundice was a granulomatous cholangiolitic or pericholangiolitic and partially xanthomatous liver disease Since the bile retention was caused by obstruction of the smallest intrahepatic bile ducts, it is understandable that the cholecystogastrostomy was ineffective and that jaundice persisted Later symptoms appeared that indicated hemorrhagic diathesis

The exact cause of xanthomatous biliary cirrhosis is unknown, but the inflammatory blockage of the junction between the intra-acinary bile capillaries and the interlobular bile ducts may be the key point The granulomatous process there becomes complicated by the simultaneous disturbance in the lipoid metabolism The author does not believe, however, that the disturbance in the lipoid metabolism is the initial factor The histological changes in the liver seem to represent an atypical, cholangiolitic biliary cirrhosis, and only exceptionally, may the process be characterized by transient honeycomb structures in the cholangiolitic granulation tissue The changes in the tissues might then resemble those in lipoid nephrosis First the epithelia of the junction ducts and of the terminal bile ducts become loaded with the flood of lipoids and finally degenerate and adjacent histiocytes absorb the liberated cholesterols so that epithelial and mesenchymal honeycomb cells appear Excessive production and retention of lipoids produce the hyperlipoidemia, and this, in turn causes the deposition of the adventitial histiocytes in various locations, particularly in the skin The fact that the cholesterol metabolism in women is unstable because of endocrine factors, particularly during the menopause, may explain the predisposition of women to xanthomatous biliary cirrhosis As a counterpart to this disease, in which an unknown pathogenetic factor seems to act chiefly in the smallest intrahepatic biliary passages, the author describes the case of a 74-year old woman who had had recurrent attacks of jaundice since the age of 18 In this patient extraordinary proliferations of honeycomb cells were found in the larger interlobular bile ducts The changes in this patient were due to an entirely different process Here there existed chronic, sometimes suppurating intrahepatic cholangitis with pseudoxanthomatous pericholangitis

Alcaligenes Faecalis and Human Pathology A Study of 80 Strains E Enjalbert L Lapchine and Tran-Van-Tho Toulouse med 58 45 60 (Jan) 1957 (In French) [Toulouse France]

Contrary to the general assumption that Alcaligenes faecalis is a normal saprophytic inhabitant of the intestinal tract in man and animals, the authors emphasize that it is an abnormal inhabitant of the intestines in man and that it is associated with various infections Eighty strains of this organism were isolated from the blood, spinal fluid, endobronchial biopsy specimens, pleural fluid, urine, throat smears, and feces of patients with sore throat, meningitis, bronchitis, tuberculosis, cancer of the lung, suppurative conditions, and gastroenteritis The sensitivity of 65 of the 80 strains to antibiotics was tested, 13 strains were resistant to all the common antibiotics, 4 were sensitive to penicillin, 36 to chlortetracycline, 39 to chloramphenicol, 47 to oxytetracycline, and 23 to streptomycin Clinically, chloramphenicol had the most rapid effect A faecalis has been erroneously considered by other workers as a 'contamination" of the examined specimens It is the only one of the Achromobacteriaceae associated with acute generalized infections of the typhoid type and with various localized infections in man Spontaneous recovery occurs frequently, and one should refrain from treating the infection too rapidly and too vigorously Even recovery from the acute meningitis occurs more easily than from meningitis caused by other gram-negative bacteria Localized infections require treatment with an effective antibiotic, but the causative agent is rapidly destroyed when it is reached by the drug The risk of the appearance of more and more dangerous resistant strains after prolonged treatment with antibiotics is less of a threat with A faecalis than with other bacteria such as Proteus and Pseudomonas, and it does not seem that the part played by the antibiotics is a very disturbing one

Dangerous Irregular Blood Type Antibodies Report on Danish Material Comprising 450,000 Blood Specimens J Andersen and G Munk-Andersen Ugesk læger 119 31-37 (Jan 10) 1957 (In Danish) [Copenhagen]

Examination of 450,000 blood specimens, 125,000 of them from pregnant women, for the occurrence of dangerous irregular-blood-type antibodies revealed anti-Rh, antibodies to D, CD, and DE, in 2,007 persons and antibodies to C, E, c, e, f, K, S, Fy^a, and Jk^a in 100 persons On the basis of the frequency of immunization recipients for blood transfusion are divided into 3 categories, (1) especially exposed recipients—persons previously given transfusion and women who have given birth to children with signs of hemolytic disease or whose history is suspect in this regard, (2) less exposed recipients—women who have been or are pregnant but have not born children with signs of hemolytic disease, and (3) ordinary recipients In group 1 the frequency of all immune antibodies is especially high, and these patients should therefore be given transfusion only after an extended compatibility test In group 2, although an extended compatibility test is not so necessary, it should be made In group 3 the classic compatibility test in object glass suffices The practical value of the group classification of recipients depends on how carefully the history of transfusion and pregnancy is taken Persons in whom an irregular immune antibody has previously been established, including anti-Rh, constitute a special group in which blood transfusion should be given only after an extended compatibility test even though it is a matter of donors found to be negative with regard to the blood type characteristic involved

RADIOLOGY

Bone Lesions in Patients with Irradiation Ulcers J Kolár and R Vrabec Strahlentherapie 102 112-125 (No 1) 1957 (In German) [Munich, Germany]

In 34 patients with irradiation ulcers the authors studied the condition of the bones underneath these ulcers In 24 the irradiation had been given for tumors In 5 the irradiation ulcers appeared 3 months after the last irradiation whereas in the others the interval between irradiation and ulceration ranged from 1 to 15 years, averaging about 6½ years In 11 of the patients the bone lesions involved the thorax (ribs or sternum), in 9 the pelvis (mostly the neck of the femur), in 6 the extremities, in 5 the vertebral column, and in 3 the skull Roentgenologic examination does not reveal the serious histological changes, furthermore, as with the skin lesions, the irradiation damage in the bone may progress for years Neither the onset nor the ultimate prognosis of the bone lesion can be ascertained The authors observed the following bone lesions osteoporosis, structural transformation of the substantia spongiosa and corticalis, well-defined or indistinct areas of decreased density, Sudeck's bone atrophy, spontaneous fractures, and necrosis and destruction of bone and cartilage

Factors that differentiate bone lesions produced by irradiation from those resulting from metastasis included localization in the irradiated region and the absence of similar lesions in other bones, slow progression and sometimes a tendency to cure, not taking place spontaneously in metastases, benign nature of the lesion as proved by the fact that of 24 patients in whom tumors were irradiated 18 have so far survived more than 5 years, and the fact that renewed irradiation increases the bone lesion Biopsy furnishes further proof but the authors avoid it because of the risk of infection in the necrotic bone Conservative treatment was used in 5 patients but proved ineffective in 2 In 29 patients plastic repair was carried out, and in 6 of these necrotic bone had to be removed Necrosis in transplanted tissues and wound infections demonstrated that the vitality of the tissue was greatly reduced

Clinical Aspects and Therapy of Melanomas G Miescher Strahlentherapie 102 1-20 (No 1) 1957 (In German) [*Munich, Germany*]

Miescher designates the malignant form of the proliferation of melanoblasts as melanomalignoma, pointing out that this term should replace the terms melanocarcinoma and melanosarcoma In the development of melanomalignomas the precancerous, circumscribed melanomas are important They generally appear as pigmented spots that are characterized by extreme irregularity of contour and pigmentation They may contain not only brown but also gray-brown and blue-black pigments These pigmented spots may appear also on the mucosa Melanomalignomas may develop from them after many years The decision of whether malignancy exists may prove difficult, but it is inadvisable to attempt clarification of the diagnosis with biopsy, because this involves the danger of metastasis

Opinions are still divided about the treatment of the melanomalignomas, some regarding resection and others irradiation as the treatment of choice In the author's series of 98 patients, 74 were still free from metastases when last seen These patients were treated during different periods, and in some the primary treatment was resection and in others irradiation The results obtained indicate that the presence of metastases at the time of treatment is the most important factor in the prognosis Melanomalignomas are curable in a high percentage of cases, provided treatment is started before the development of metastases Neither the surgical nor the radiologic method is necessarily superior, provided either method is carried out appropriately In the treatment of difficult cases, surgeons and radiologists should collaborate Although the treatment of the melanomalignomas is difficult, this is not the case in the precancerous melanotic stage In 37 patients with such lesions the author achieved ideal results with grenz ray therapy

ANESTHESIA

A New Technique of Treatment For Intractable Pain Prefrontal Infiltration with Procaine by Supraorbital Route J Sigwald, D Bouttier, C Piot and others Semaine hôp Paris 33 400-402 (Jan 30) 1957 (In French) [Paris]

The authors used a new technique for the relief of intractable pain in patients with cancer After local anesthesia of the roof of the orbit with a few cubic centimeters of procaine, a trocar containing a pointed stylet was inserted through the upper eyelid at a distance of about 1 cm from the outer canthus and about 5 mm below the orbital arch After the indented point of the trocar had come into contact with the bone, the stylet was pulled back, and a stainless steel bit, firmly fixed to a holder, was introduced into the lumen of the trocar in such a manner that its length did not exceed that of the trocar by more than 2 or 3 mm Thus any risk of severely damaging the substance of the brain was prevented, and the plate of the frontal bone was pierced easily, with the aid of a slightly rotatory movement The bit, then, was pulled back and replaced by a long needle with a blunt end, containing a stylet This trocar was then inserted into the frontal lobe The needle was pulled back and aspiration was performed with the aid of a syringe to make sure that the cerebral ventricles had not been affected In the absence of any ventricular fluid, 10 cc of procaine hydrochloride was injected slowly The entire procedure required 10 minutes and was repeated immediately on the other side

Twenty infiltrations were performed according to this technique with excellent results in 7, satisfactory results in 10, and failures in 3 Among the excellent results was that obtained in a woman with cachexia and cancer of the stomach who had obtained only little relief of pain from 3 daily injections of morphine and who became euphoric after her first infiltration with procaine hydrochloride Pain was completely relieved for 12 months A mild recurrence was controlled with another infiltration, and she survived for a year without suffering Other patients were greatly improved so that morphine injections were required less frequently or morphine treatment could be discontinued completely In most patients, improvement, however, was only temporary and another infiltration became necessary after from 8 to 15 days It was repeated 3 or 4 times before complete failure became apparent Neither mental disturbances or disturbances of character occurred in any of the patients Syncope occurred in 1 patient and apparently was caused by the passage of a few drops of procaine hydrochloride into one of the lateral ventricles Mild headache for several days was observed in a few patients A severe cerebral hemorrhage occurred in 1 patient with cancer of the stomach who was in poor condition on admission The prefrontal infiltration was done with the aid of general anesthesia and displacement of the trocar in the frontal lobe resulted from an inopportune movement The patient became semicomatose after the infiltration and died the next day Autopsy revealed a hematoma the size of a nut in the injected prefrontal lobe

PHYSIOLOGY

Physiology and Toxicology of Tritium in Man E A Pinson and W H Langham J Appl Physiol 10 108-126 (Jan) 1957 [Washington, D C]

Tritium was used as a tracer for hydrogen of mass one (protium) in biological experiments The advantage of tritium over deuterium is that it is radioactive The rate of entry of tritium into the body as water (HTO) and as gaseous hydrogen through the principal routes, the rate and extent of distribution and fixation of tritium in tissues in various parts of the body, and the rate of tritium excretion were studied on the basis of 5 experiments on 3 normal men, for the evaluation of the health hazards to personnel exposed to tritium either chronically or acutely in laboratories or industrial plants HTO absorption through the gastrointestinal tract was complete in 40 to 45 minutes The volume of water transferred from the intestine to the blood was linear with time and proportional to the volume of water ingested within the range of 100 to 1,000 ml When exposed to HTO vapor by inhalation, man absorbed 98 to 99% of the radioactivity inspired

The activity in venous blood increased steeply during and shortly after exposure to the inhalation of tritium Then it declined exponentially to equilibrium with a half time of about 12 minutes The average dilution volume was 62 2% The biological half time of tritium in the body fluid of 8 men on ad libitum water intake averaged 11 5 days HTO was absorbed by man through the skin at a rate comparable to that of insensible perspiration at equal vapor pressures The HTO entering the body through the total skin was about equal to that entering the lungs Man slowly oxidized inspired protium-tritium molecules to HTO The radiation hazard from exchange of tritium with hydrogen of the tissues after exposure to HTO was insignificant compared to the hazard from the amount of HTO necessary to induce appreciable radioactivity in the tissues The maximum permissible concentrations of tritium oxide in air and water was estimated at 5×10^{-6} μc per milliliter and 0 1 μc per milliliter respectively for continuous 24-hour exposure Adoption of the recommendations of the International Commission on Radiological Protection will result in the division of these values by 3 and the maximum permissible body burden of tritium will become about 1 2 mc

The Effect of Adrenaline Infusion on Human Blood Coagulation G D Forwell and G I C Ingram J Physiol 135 371-383 (Feb 15) 1957 [Cambridge, England]

Experiments performed by Cannon and co-workers in anesthetized animals in 1914 revealed a shortening of the clotting time after the administration of epinephrine The main experiments of these workers were repeated by the authors in anesthetized cats and dogs By using Cannon's technique, his observations were confirmed, but the results obtained with this technique could not be reproduced with standard methods It remains, therefore, uncertain what function of clotting Cannon may have measured Of 22 male volunteers in whom clotting times in silicone-coated tubes and direct eosinophil counts were obtained by serial venipuncture at half-hour intervals, 8 drank a solution of 50 Gm of fructose after the 1st venipuncture and 14 received instead 50 Gm of destrose Blood dextrose and fructose concentrations were also determined A correlation between the clotting time and the eosinophil count was observed in these men This suggested that the effect of repeated venipuncture was an important variable in experiments comparing the clotting of consecutive blood samples and that the effect might be assessed by the behavior of the eosinophil count

Twelve control infusions and 13 epinephrine infusions then were given to 9 healthy young medical students who were well-habituated to venipuncture The difference in clotting time between blood samples obtained from venipuncture before and after the infusions of epinephrine was compared with the difference in clotting time between blood samples obtained from consecutive venipunctures spaced at about the same intervals during the control infusions Only after the epinephrine infusion was a significant fall in clotting time demonstrable in the silicone-coated tubes This was not seen in the glass tubes This finding suggested that the fall in clotting time was a real effect of the epinephrine and that the effect of the drug was mediated through the initial stages of clotting not later than the development of intrinsic thromboplastin More detailed studies of the clotting mechanism were made after 7 of the epinephrine infusions, and the results suggested an increase in the activity of clotting factor 5

Observations on a Case of External Pancreatic Fistula in Man I S R Sinclair Brit J Surg 44 250-262 (Nov) 1957 [Bristol, England]

Physiological responses of the pancreas were studied in a 47-year-old man in whom a pancreatic fistula developed after subtotal gastrectomy for duodenal ulcer The daily output of pancreatic juice seems to be greater than has often been taught, 1,500 ml is not considered indicative of pathology The rate of pancreatic secretion fell to levels lower than those previously recorded in man This slight secretion is considered to be mainly the result of continuing stimulation by the vagus The sodium concentration in the pancreatic juice is higher than that in the serum The low estimates of calcium concentration in the pancreatic juice given by some previous workers may be explained on the basis of a technical error in the method of estimation The reciprocal relationships between chloride and bicarbonate concentration were confirmed and some evidence is presented that a similar relationship exists between sodium and potassium ions

Attention is drawn to the dissociation between the volumetric and bicarbonate responses after stimulation of the pancreas In general the responses to various drugs confirmed previous reports, but the effect of prostigmine was variable and in tests of pancreatic function this drug should not be used to stimulate secretion Various pure foodstuffs were tested as stimulants of pancreatic secretion Carbohydrate proved a much more powerful stimulant than either protein or fat Administration of carbohydrate directly into the jejunum resulted in a brisk flow of pancreatic juice Intravenous infusions of carbohydrate or protein hydrolysates did not stimulate pancreatic secretion The absence of a psychic phase of pancreatic secretion in man was confirmed, as was the failure of the broad-spectrum antibiotics to reach the pancreatic juice

Divergent Results in Sex Determination on the Nuclei of Leukocytes and of Oral Epithelial Cells W Kosenow Klin Wchnschr 35 75-76 (Jan 15) 1957 (In German) [Berlin]

Kosenow points out that, whereas at first skin biopsy was resorted to for the determination of the sex chromatin, it is now customary to search for the differentiating sex chromatin in the nuclei of leukocytes and of oral epithelial cells (obtained by means of a spatula from the buccal mucosa) These latter methods are preferred because they obviate the need for biopsy On the other hand these methods represent an additional means of verification In all tests on healthy children the diagnosis 'chromosomal male" and "chromosomal female" corresponded with the true sex Of 15 phenotypically female patients with gonadal dysgenesia, 11 proved to be genetic males and 3 genetic females on the basis of the sex chromatin in the nuclei of the oral epithelial cells as well as of the leukocytes in blood smears

The one exception was an 18½-year-old girl of low stature (32 cm [12½ in] below normal) with hypogenitalism and skeletal changes in the form of osteoporosis, scoliosis, and retarded development of the centers of ossification of the bones of the wrist No ovaries were found at laparotomy In this patient blood specimens (nuclei of leukocytes) were repeatedly examined for the sex chromatin (always by 2 examiners) The quantitative occurrence of the mass of chromatin indicated that this patient was a chromosomal male The results of the search for the sex chromatin in the nuclei of the oral epithelial cells, however, gave a decidedly different result Three investigators examined specimens from the oral mucosa of this patient, counting 200 cells, and found 22, 16, and 25 with chromatin-positive (female) nuclei While these figures are below the averages obtained by other investigators, the authors believe that they indicate a 'chromosomal female" About 10% of the chromatin positive cellular nuclei had not only 1 but 2 chromatin bodies The search for the double sex chromatin was made by 2 investigators both of whom found that 9 or 10 of 100 cells whose nuclei contained the sex chromatin had 2 masses of female sex chromatin The divergent results of the 2 methods in this patient cannot be explained by the authors They believe that this observation demonstrates the importance of always making several tests before making a diagnosis of the chromosomal sex in patients with gonadal dysgenesia They also suggest that studies be made on a larger number of such patients to ascertain whether the observed divergence of test results is due to technical defects or whether different combinations of sex chromosomes or anomalies of the accessory chromosome exist, which might throw more light on such abnormalities

Individual Variations in Expenditure of Energy J Booyens and R A McCance Lancet 1 225-229 (Feb 2) 1957 [London]

It has generally been accepted that variations in individual caloric intakes are due to differences in age, size, and muscular activity at work and recreation, tempered to some extent by the degree of efficiency and training of the subject It has also been shown that in any homogeneous group of adults or children, there are always some who have caloric intakes greatly in excess of those of others and that the differences cannot necessarily be explained by size or observed muscular activity The results of investigations had indicated that differences in the energy expended during lying and sitting might be responsible for large individual variations in caloric intake, and it was suggested that similar differences might underlie the facility with which some people appear to put on weight, whereas others do not The authors checked the findings of other investigators and studied the caloric expenditures of some people who utilize large or small amounts of energy when they are lying, sitting, and standing Their studies were made on 14 women and 22 men, ranging in age from 20 to 57 years Apart from a few science students, all the subjects were attached to the Department of Experimental Medicine and were accustomed to the idea of experimental work, hence psychological influences were largely eliminated The metabolic rates were determined while the subjects were (1) in the basal state, (2) sitting on a comfortable upright chair, and (3) standing Three had rates more than 30% below and 1 a rate of more than 24% above the average for the group for all 3 occupations

The energy balance sheets of these 4 and of 2 other persons were investigated for 7 or 14 days The intake was measured by weighing the food and the output by a time-and-motion study, combined with measurements at the important occupations It was concluded that (1) the limits usually accepted for the normal basal rates are too narrow and (2) an unusual rate for lying, sitting, and standing may make a great difference to the total daily expenditure of energy, but (3) although a small expenditure at these 3 occupations may lead to a small energy requirement, it does not necessarily lead to obesity or even to a tendency to put on weight It was thought at the outset of this study that if persons were found with exceptionally low metabolic rates lying, sitting, and standing they might all tend to be fat and have trouble in keeping their weight within normal bounds Two subjects were found to have this trouble, but 2 others were both exceptionally thin and did not have to worry about the food they ate in spite of their low metabolic rates One man who had a high metabolic rate while lying, sitting, and standing was large and maintained his weight easily Another subject was a woman of normal proportions These masked variations in expenditures of energy explain well enough why some people require few calories to maintain their weight and others twice as many, but there is nothing to suggest that they play any part in the fundamental control of appetite This problem remains to be solved 'The food served in the society in which we live and the food eaten by habit and convention are adjusted unconsciously to suit the person who is average in all respects Persons with low expenditures of energy, whether obvious or masked, can only maintain or retain an average weight if they stop eating the strictly conventional amounts of food

PUBLIC HEALTH

Study of Antipoliomyelitis Antibodies in Children and Young Adults in the Canton of Vaud B Baudiez, V Bonifas, C Piguet and C Wild Schweiz med Wchnschr 87 77-81 (Jan 26) 1957 (In French) [Basel, Switzerland]

In the spring of 1955, the health authorities of the canton of Vaud undertook a preliminary immunological investigation designed to facilitate the choice of candidates for antipoliomyelitis vaccination The presence or absence of the 3 types of antipoliomyelitis antibodies was investigated in (1) school children, aged 7 or 8, (2) school children, aged 11 or 12, and (3) normal-school students, aged 18 or 19 Groups 1 and 2 were subdivided into rural and urban subgroups The percentage of children in the 7-to 8-year age group with antibodies of at least 1 type was significantly higher among the rural than it was among the urban children, 76% as compared with 61% A significant difference was also found between the town and the country children in regard to the number of those in the 7 to 8-year age group with both type 1 and type 3 antibodies In the 11-to-12-year age group, the difference was no longer significant

Infection with 1 type of poliomyelitis virus is known to produce specific antibodies capable of neutralizing, in vitro, only that particular type of virus The findings in clinical cases, however, suggest that there is a certain degree of cross protection so that an earlier infection with a type 2 virus provides some protection against the paralysis caused by a type 1 infection The percentages of persons immunized against all 3 types of virus in this study were 4 2% for children aged 7 or 8, 14% for children aged 11 or 12, and 6% for young adults aged 18 or 19 Analysis of the distribution of antibodies in relation to age showed that in the 11-to-12-year and 18-to-19-year age groups, 1 in every 5 inhabitants of the canton possessed no antipoliomyelitis antibodies and so ran the risk of contracting poliomyelitis in case of exposure to the virus Since the relation between clinically manifest poliomyelitis and inapparent cases in persons exposed for the first time to the virus increases with age, it follows that the danger of contracting paralytic poliomyelitis increases between the ages of 12 and 18 The serologic findings in this series support the endemoepidemiologic observations in the canton in recent years in which almost as many cases of paralytic poliomyelitis have been found in adults as in children

The study of serologic immunity shows that a certain number of the persons in a population are not protected against poliomyelitis A population normally lives in a state of equilibrium in relation to the poliomyelitis viruses, with only a small proportion of the nonimmune persons contracting the disease The equilibrium, however, may be disturbed so that from time to time the incidence of the disease rises, although the distribution of cases by age groups remains unchanged Antipoliomyelitis vaccination is indicated as a matter of principle because the conditions that may lead to an increase in the incidence of the disease are not subject to control, and the findings in this study suggest that young children, because they are the most susceptible to infection, should be the first to be vaccinated

Ethnic Differences in the Incidence of Leukemia B MacMahon and E K Koller Blood 12 1-10 (Jan) 1957 [New York]

That leukemia is recorded as cause of death less frequently among American Negroes than among white persons has been well authenticated The authors made an attempt to estimate the incidence of leukemia in relation to religion and country of birth, using data collected from clinical records and death certificates in Brooklyn A series of 1,636 white patients in whom leukemia was diagnosed in the period 1943-1952 is compared with selected census data for the population The incidence of leukemia in the native population of Brooklyn was 45 3 and in the foreign-born population 61 0 per million per annum The large proportion of Russian-born persons in the population seems to account for the higher rate in the foreign-born group Catholic and Protestant groups did not show any difference in susceptibility to this disease United States vital statistics show that the commonly observed difference in leukemia death rates between white persons and Negroes is associated with social differences between the 2 groups Little or no difference in leukemia death rate was seen between these 2 groups in Brooklyn

BOOK REVIEWS

Wire Brush Surgery in the Treatment of Certain Cosmetic Defects and Diseases of the Skin. By James W. Burk, Jr., M.S., M.D., Associate Professor of Clinical Medicine (Dermatology), Tulane University of Louisiana, School of Medicine, New Orleans. Publication number 300, American Lecture Series, monograph in Bannerstone Division of American Lectures in Dermatology. Edited by Arthur C. Curtis, M.D., Chairman, Department of Dermatology and Syphilology, University of Michigan Medical School, Ann Arbor. Cloth. $6.75. Pp. 154, with 68 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1956.

This monograph presents an inclusive, well-illustrated, and readable summary of the current status of dermabrasion for scarring and other skin changes, with particular reference to scarring following acne. The author has summarized the literature on the subject adequately, and has written his book from a background of personal experience. There is a digest of the anatomic and histopathological principles that bear on the procedure and a detailed outline of the equipment and supplies required, the comparative virtues of ethyl chloride and Freon 114 for producing freezing and local anesthesia, the techniques of the method, postoperative management, complications, indications, and contraindications.

The essential procedures and instruments for carrying out dermabrasion were described in several publications by Kromayer in Germany, in 1905. Curiously enough, his methods appear to have received little or no trial in the United States until the reintroduction of the sand-papering technique in the mid-1940's. This technique had a number of disadvantages, one of the most serious of which was the formation of silica granulomas in the abraded area. The late Dr. Abner Kurtin of New York repopularized and refined the method of dermabrasion, and must be credited with the development of the technique as it is used today by dermatologists and plastic surgeons. From its original restriction to the treatment of scars from acne, chickenpox, or trauma, and attempts at removal of tattoo marks, the method has been widely extended to include treatment of various benign epidermal tumors, rhinophyma, and many of the excrescences and other morphologic changes of aging.

On the basis of thousands of cases of acne scarring treated by this method since 1953, there can be no doubt that significant cosmetic improvement can be obtained in well-selected cases, and that the risks are relatively small in the hands of competent operators. The human skin, fortunately, is endowed with extraordinary self-reparative powers. Because the epidermal pegs extend deeply into the skin in most areas, the epidermis is capable of regrowing after vigorous abrasion, even to the point of exposure of small islands of subcutaneous tissue. If it is then let alone, and does not become infected or undergo hypertrophic scarring, the surface of the regenerated skin looks better than it did before.

The author is well aware of dangers of overenthusiasm in any surgical procedure undertaken to remedy a cosmetic defect. However, the risks of the method are so small and the improvement so definite as to justify its use in patients who have significant scarring following acne or some other inflammatory process. There can also be little objection to the use of the method in obviously benign epidermal tumors such as seborrheic keratoses. In the case of tattoo marks, in which the pigment is subepidermal, the method is far less successful. Its use in improving the wrinkling of age and in removing freckles and other melanin pigmentary deposits should be approached with great caution. In the case of pigmented nevi, the author states that, "with the exception of obviously benign non-pigmented nevi, a punch biopsy should precede planing." The only difficulty with this concept is that the gross criteria for recognition of nevi of junction type, either inactive or active, are still not as clearly defined as they might be. It is reassuring that no undetected melanomas have been reported after the use of this method, but certainly it cannot be regarded as an acceptable method of removal of pigmented nevi. As a commentary on the bacteria-laden environment of hospitals, the author reports that the two instances of postoperative infection he encountered occurred in hospitalized patients. He regards outpatient treatment as preferable. This is a balanced and informative book.

Chronic Illness in the United States. Volume II. Care of the Long-Term Patient. By Commission on Chronic Illness. Cloth. $8.50. Pp. 606, with illustrations. Published for Commonwealth Fund by Harvard University Press, Cambridge 38, Mass.; Oxford University Press, Amen House, Warwick Sq., London, E.C.4, England, 1956.

This is the second volume in a series of four reports by the Commission on Chronic Illness. The Commission is sponsored by the American Hospital Association, the American Medical Association, the American Public Health Association, and the American Public Welfare Association. Thirty-nine other national organizations in the health field participated in the 1954 conference, the conclusions of which are the basis for the observations and recommendations appearing in this volume. The book's eight chapters deal with the long-term patient, the patient at home, rehabilitation at home and in institutions, the patient in an institution, personnel and education, coordination and integration, research for planning and administration, and financing. Seven appendixes deal with special phases of the general subject.

The "long-term patient" needs definition. Not all who are afflicted with chronic disease need constant or regular medical care. As defined by the Commission, a long-term patient is one suffering from chronic

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

disease or impairment, who requires a long period of care for a continuous period of at least 30 days in hospital or three months in an institution or at home and who requires medical supervision It is estimated that there was possibly an average of 5,300,000 persons who were disabled for longer than three months in 1950 These persons constituted 3 5% of the total population Of these, about 4,200,000 were at home, and 2,120,000 were 65 or older It would be beneficial to know how many of these could be rehabilitated to the point of reasonable self-sufficiency The patient should be able to provide himself with the basic needs of food, shelter, and clothing Those who can reach this level of self-sufficiency will give the greatest reward for the cost and effort involved

On the other extreme we number those whose condition is irreversible For these, mostly psychotic, paralyzed, arthritic, tuberculous, deaf, blind, or feeble minded, domiciliary care under institutional supervision seems the best that can be done The Commission discusses what should constitute minimal acceptable care and attention and applies this ideal as the minimum for everyone One can agree to this ideal while questioning its practicability To build and equip the facilities and to train the nurses and 35 kinds of technical personnel required—the services of one or more of which will be needed during the course of chronic illness—is beyond the fiscal capacity of private charity or the taxpayer Taxes from local, state, and federal governments already take about 33% of earnings The only reference to a fiscal plan to implement the Commission's recommendations appears on page 441 (paragraph 69-b)

> Until the time when the needs of all long term patients are adequately met under plans and programs listed here, there is no alternative to the basic proposition that society as a whole through taxation must meet the deficit and fill the gap Funds for this purpose should be provided by local, state and federal taxation Medical care of the long term patient currently is financed in a variety of ways through direct personal financing, voluntary health insurance, philanthropic agencies, workmen s compensation, non occupational disability insurance, industrial medical care programs and tax funds

The authors are to be commended for their thorough explanation of the many factors involved They have defined long-term patients and subdivided this group according to dominant causative characteristics This breakdown indicates which of these persons can be rehabilitated in whole or in part They are the ones for whom the expenditure of more funds can be justified from the standpoint of economy The long-term patient who can be returned to productive living ceases to be a long-term expense

Biochemical Individuality The Basis for the Genetotrophic Concept By Roger J Williams, Professor of Chemistry, Director Biochemical Institute University of Texas Austin Cloth $5 75 Pp 214, with 17 illustrations John Wiley & Sons, Inc , 440 Fourth Ave New York 16 Chapman & Hall, Ltd , 37-39 Essex St , Strand, London, W C 2, England, 1956

In this volume the author stresses the importance of the uniqueness of the individual as opposed to the similarity between individuals If one considers the wide variations existing in many clinical values in the so-called normal person, it becomes readily apparent that, when extremes are persistent in normal persons, these individuals differ profoundly even though clinical values are within the normal Such differences are not surprising when one considers the numerous enzymatic reactions controlling body functions and the results when several of these reactions are functioning other than optimally

The first two chapters may be considered introductory, in that the author establishes the significance of biochemical variation and the basis for biochemical individuality The next eight chapters point out areas of existing individuality in anatomy, chemical composition of the body, enzyme patterns, endocrine activity, excretion patterns, drug response, and nutrition The latter area includes a discussion on the amounts of inorganic and organic constituents present in the body and the quantities of each required by individuals A single chapter containing a miscellaneous group of areas of individuality is also included In chapter 11 the author explains the genetotrophic concept as based on biochemical individuality The principle simply stated by the author is "Every individual organism that has a distinctive genetic background has distinctive nutritional needs which must be met for optimal well-being " The final three chapters contain ideas with respect to the implications this concept has in the biological sciences, medicine, dentistry, and psychiatry The book makes interesting reading because of the freshness of the concept it contains and the immense areas it opens in both fundamental and applied research It contains pertinent technical references at the end of each chapter and a general subject index

Training of the Lower Extremity Amputee By Donald Kerr B B A , Director, National Institute for Amputee Rehabilitation Lodi N J , and Signe Brunnstrom, M A Consultant in Amputee Training, Institute of Physical Medicine and Rehabilitation, New York University–Bellevue Medical Center, New York Introduction by T Campbell Thompson, M D Cloth $6 50 Pp 272, with 153 illustrations Charles C Thomas, Publisher, 301-327 E Lawrence Ave Springfield, Ill , Blackwell Scientific Publications Ltd , 24-25 Broad St , Oxford, England, Ryerson Press, 299 Queen St , W , Toronto 2B, Canada, 1956

Donald Kerr, himself an above-knee, lower extremity amputee, and the co-author state that their reasons for preparing this book were to inform the surgeon about rehabilitation of the amputee, to inform the nurse on stump care, to give the physical therapist a program of preprosthetic care and techniques for training the amputee, to inform the limb maker about stump care and training techniques, and to instruct the amputee in preprosthetic care, selection and testing of the prosthesis, and exercises in its use The book is well illustrated Its 12 chapters are entitled (1) Adjusting to the Amputation, (2) Pre-prosthetic Period, (3) Lower Extremity Prostheses, (4) Stump Socks and Dressing Hints, (5) The Single Above-Knee Amputee Training, (6) The Single Above-Knee Amputee Walking, (7) The Single Above-Knee Amputee Daily Activities, (8) The 'Tilting Table" Amputee Training Methods, (9) The Single and Double Below-Knee Amputee Training Methods, (10) The Double (One Above and One Below-Knee) Amputee Training Methods, (11) The Double Above-Knee Amputee Training Methods, and (12) Social Dancing and level is within normal limits, thyroid therapy is not indicated If, however, the blood cholesterol level is high and the protein-bound iodine level is low, thyroid in proper doses to bring the basal metabolism rate to normal may be indicated Weight reduction should assist greatly in returning the blood pressure toward normal Use of the various types of ganglionic blocking agents, such as pentolinium and hexamethonium compounds, should be reserved and employed only if weight reduction and other measures are not successful in bringing down blood pressure

X-ray study of the skull to rule out possible lesion in the hypothalamus or pituitary region should be done Emphasis should be placed upon providing an attractive and prolonged weight-reduction program through dieting Lean meat and other protein foods should be taken in fairly generous amounts Bulky foods, such as salads, fruits, and vegetables, should be provided generously Sweets, starches, and fats, in general will have to be greatly curtailed Bread, preferably as whole wheat bread, one slice at a meal is allowed A multiple vitamin capsule will insure adequate vitamin intake Psychological factors should be investigated Frequently the cause of excessive caloric intake over a long period of time is psychological Pleasure in eating may become a dominant personality trait and may serve as a substitute when social, business, or sexual desires are unsatisfied Obesity itself may be used as a weapon against undesired demands of work, family, or community Corpulence may serve as a guard against frustrations resulting from loss of physical attractiveness and efficiency Problem children often become obese and use the condition to demand special attention In a great majority of cases of obesity both physiological and psychological abnormalities are factors in causation of the obese condition Individual study in each case is necessary to discover the causes, which are usually multiple

ALLERGIC DERMATITIS IN A MEAT PACKER

To the Editor —*A 32-year-old woman who has been wrapping meat for five years in a chain grocery developed an eczematoid dermatitis, obviously of an allergic nature, on the ventral surface of both arms (she works in a short-sleeved uniform) and on the neck and upper part of the thorax The eruption is macular and bright reddish at its height, on one occasion it progressed to a weeping stage Antihistamines and cortisone cause prompt remissions, but when she returns to work the process begins again after about one week Itching is present The wrapping of meat entails the use of cellophane paper When the paper is folded around the meat and creased, the operator irons it with a hot iron This produces a sealing of the paper and also produces a smoke that envelopes the operator Incidentally, there is an almost constant sore throat" Is this patient reacting to the fumes produced by this process on these papers?*

Benjamin L Camp, M D, Atlanta, Ga

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —It is impossible to diagnose a dermatitis from a description and a history However, the concept that the dermatitis in this patient might be due to an external contact seems reasonable Furthermore, the idea that it might be due to exposure to a chemical or a fume is suggested by the distribution of the eruption and the history of exacerbations on return to work However, to establish the cause, patch tests would be necessary Contact dermatitis is not common in meat wrappers Eruptions due to cellophane are also unusual Cellophane is used in performing patch tests because it is nonirritating It is desirable to have a clear area, free from dermatitis, between the tape, which is so often irritating, and the tested substance Cellophane is ideal for this purpose Reports of cellophane toxicity could not be found in the available literature, except that Hunter (Diseases of Occupations, Boston, Little, Brown & Company, 1955) quotes an inconclusive personal communication from Flinn (1943), who claimed to have produced paralysis of the wings and legs of domestic fowl fed cellophane for 28 days Schwartz, Tulipan, and Peck (Occupational Diseases of Skin, ed 2, Philadelphia, Lea & Febiger, 1947, p 525) state that industrial dermatitis does not occur in cellophane workers It must be admitted that sensitization could develop to the fumes emanating from the heated cellophane However, the physician must consider other possible causes, such as plants, insecticides, other chemicals, detergents and photosensitization Despite the suggestive history, the actual cause may have nothing to do with her task of wrapping meat Other substances in her vicinity or agents contacted away from work might be at fault Therefore, it must be reiterated that careful patch test studies on this patient to determine the exact cause is imperative before a definite decision can be rendered If patch tests with the cellophane used in her work are negative at normal temperatures, controlled exposure to the fumes should be attempted It might be worth mentioning that this consultant has seen a similar case in which the actual cause was found to be sensitivity to external contact with beef Another possibility to be considered would be that the patient is not using cellophane but is exposed to another similar product containing sensitizing chemicals This should be checked with the manufacturer

Answer —It may be doubted that cellophane itself may be the source of the conditions described There is the remote prospect that some plasticizer or moisture-proof agent when added could induce the affections This must be tested through the application of appropriately applied closed skin patch tests In some such tests, when allergy is suspected, the material should be kept in place for longer than customary periods and up to 96 hours This being true, several samples of the mentioned materials should be applied in order that one may be removed at the end of 8, 24, 48, and 96 hours The test materials should include cellophanes as such, but other tests should make use of the same items applied promptly after more heating than is required in the work operation Likewise, these samples should be removed at different periods up to 96 hours unless earlier-removed patches indicate positive responses. Wholly negative results should go far in exculpating cellophane as the ffender. A common source of dermatitis in butchers, nd notably fish butchers, is the erysipeloid organism Erysipelothrix rhusiopathiae. The cleaning agents utilized around meat blocks and counters are a more likely source of dermatitis than cellophane.

PREGNANCY IN PRESENCE OF MYOMAS

To the Editor.—*A 32-year-old married woman has been having intermittent functional bleeding for the past six months. This has been somewhat worse lately. A careful dilatation and curettage was done five months ago, and a cervical polypus was removed. The patient has multiple small fibroid tumors of the uterus that can be palpated through the abdominal wall. She has a mild mastitis, especially in the left breast, which is sore around her menstrual time. She has been married only a short time, and she wishes to have children. Should the patient be allowed to become pregnant, or should a hysterectomy be done, with complete removal of the fibroid tumors? Although the tumors are small, there is still the problem of functional bleeding. A roentgenologist strongly advises against x-ray therapy in view of recent knowledge of the possibility of mutations in the second generation.*

Hamlin B. Lindsay, M.D., Washington, Ind.

This inquiry has been referred to two consultants, whose respective replies follow.—Ed.

Answer.—The patient poses several different problems, and additional information would be of value. It would be well to know how long she has been married and the histology of the specimens removed by curettage. The chief problem seems to be uterine bleeding and the question of fertility is unanswered. It is to be hoped that the patient might get pregnant without operation, and she could probably go to term. Any operation undertaken should have as its objective the possible relief of bleeding, without interfering with the possibility of pregnancy. The possibility of myomectomy immediately suggests itself if the bleeding is debilitating or if the tumors are growing rapidly. It is possible to remove many fibromyomas, including submucous, and preserve a uterus that is capable of impregnation and maintaining pregnancy. With tumors, especially submucous, it is more likely that the bleeding is organic rather than functional. The often-associated hyperplasia of the endometrium and the possibility of adenocarcinoma with fibromyoma should be kept in mind. X-ray therapy is contraindicated in this patient. The breast complication at the menstrual time is not indicative of failure of ovulation. With definite pathology in the pelvis as described, endocrine therapy probably would not be helpful. On the basis of the information at hand, it is suggested that pregnancy be encouraged, with some assurance that if accomplished it would go to termination. If the symptom of bleeding becomes more severe, operation might be necessary; however, conservative measures should be used if possible, in the hope of preserving childbearing function. The most radical procedure would be complete hysterectomy, but it is hoped that this would not be necessary. X-ray therapy in doses large enough to cause cessation of uterine bleeding in this patient would likely produce ovarian failure and would thus eliminate any worry concerning pregnancy and mutations in the second generation.

Answer.—From the description of findings and symptoms, it would seem that hysterectomy is not necessary and that myomectomies would not be feasible. Investigation of the fertility of husband and wife should be done, followed by such treatment as may be indicated. There does not seem to be any reason that pregnancy should not be attempted.

FUNCTIONAL GASTRIC DILATATION

To the Editor.—*A 39-year-old man suffers from periodic episodes of acute gastric dilatation. This is manifested by marked bloating and is usually accompanied by copious salivation. These attacks occur particularly when the subject is under some sort of mental strain or tension. A recently performed gastrointestinal series was negative for organic pathology. Examination of the heart, lungs, and blood pressure and serologic tests are negative. Antispasmodics and sedatives have been tried, to no avail. The patient obtains some relief by lying supine. The attacks may last up to one week and cause the patient considerable anguish. He may be perfectly normal for several months at a time and then suffer another attack. Please provide suggestions as to therapy of this apparently functional disorder.*

M.D., New York.

This inquiry has been referred to two consultants, whose respective replies follow.—Ed.

Answer.—It is assumed that all possible organic conditions, even such uncommon conditions as diaphragmatic hernia, have been ruled out and that the patient's symptoms of acute gastric dilatation and marked salivation are functional or, more correctly speaking, psychogenic in origin. This impression is heightened by the fact that these symptoms occur intermittently and at times when the patient is under severe mental stress. It is a well-known fact that in states of acute anxiety or panic, symptoms of autonomic imbalance, such as dryness of the mouth and spasticity of abdominal viscera, are very common. In the case under discussion the symptoms presented by the patient, salivation and flaccidity (dilatation), although less commonly encountered, may also be ascribed to autonomic imbalance. The description of the attacks as presented strongly suggests an anxiety state; hence, a thorough psychiatric evaluation should be made. Every effort should be made to determine the psychodynamic factors that are responsible for this condition and then to institute the proper psychotherapeutic procedures. For symptomatic relief of the distressing physical symptoms, preparations of atropine and nicotinic acid may be tried.

ANSWER —The description of the symptoms, periodicity of occurrence, aggravation by mental strain and tension, and relief by lying supine suggest that this patient probably suffers from aerophagia that may be associated with a cascade type of stomach If relief is not obtained by his lying supine or in the right lateral decubitus position, it may be well to train the *patient to empty his stomach with an Ewald tube in* order to obtain immediate relief He should then be instructed in regard to a bland dietary regimen, with six small feedings daily instead of the usual three large feedings In addition to these measures, one should probably concentrate most intently on the psychotherapy of the patient and reassurance as to the functional etiology of his symptoms The patient should be instructed in regard to the mechanism of aerophagia and encouraged to make a conscious effort to refrain from air swallowing if he is ever to obtain permanent relief from his annoying psychosomatic complaint

TREATMENT OF NEVI

TO THE EDITOR —*A 50-year-old woman has been noticing a blue nevus of pinhead size on the tip of the nose and a junction nevus on her right cheek under her eye, without any changes, for about one year She would like to have both removed for cosmetic reasons Is it not a "must" to have the blue nevus removed as soon as possible? Why do dermatologists advise excision instead of cauterization? Would cauterization starting about 2 mm around the blue nevus and then going toward the nevus and under it not guarantee a sealing off (by coagulation) of any passway for the possible spreading of any cells of the nevus instead of the clean-cut wound edges and have a better cosmetic effect as well? What are the probable consequences if these two nevi are not removed? Recent articles demonstrated two cases of blue nevus in which, after removal of a blue nevus by excision (by reliable surgeons), metastatic carcinomas developed in the course of two years, although the primary tumors (nevi) had not shown any changes nor malignancy at the time of operation Please comment on these points*

M D, New York

This inquiry has been referred to two consultants, whose respective replies follow —ED

ANSWER —For the purposes of this discussion, it must be assumed that the diagnoses of 'blue nevus' and 'junction nevus' as given in the question are proved correct by histological examination It is not a 'must' to remove the blue nevus as soon as possible True blue nevi are considered to be benign lesions They are not premalignant Melanomatous degeneration in such growths is very uncommon Characteristically, malignant melanomas develop in junction nevi The latter type of tumor should be removed completely as soon as possible if it is subjected to trauma However, most junction nevi do not undergo malignant degeneration during the lifetime of the patient Therefore, there is a disagreement as to whether all junction nevi should be removed This decision must be made in individual cases by the clinician in charge of the patient or by his consultants

The type of cauterization of premalignant nevi that is condemned by dermatologists, surgeons, and pathologists refers to chemical or electrical destruction of the lesion with acid or by electrodesiccation Usually, *such destruction is incomplete It is possible* that this trauma is apt to increase the malignant tendencies of the remaining viable tumor cells Recent unpublished studies by Walton throw some doubt on this thesis However, until his experiments are confirmed by others and followed for a longer period of time and in larger series, it would be safer to assume that incomplete removal is dangerous With microscopic control, as advocated by Mohs, chemical destruction is permissible Excision is a more certain method of removing the entire tumor than the type of cauterization mentioned above and is preferred for melanomatous or premelanomatous neoplasms The excision of such a growth with a cutting cautery is another matter This is an excellent method of treating such a new growth Theoretically, the sealing of blood vessels and lymphatics by such a method is advantageous However, this advantage is more apparent than real If the nevus is removed completely by scalpel excision and the wound sutured, there should be no nevus cells left to become malignant or to metastasize to other portions of the body The only objections to cautery excision would concern comparatively erratic scarring and slow healing Such treatment might well result in a disfiguring scar on the tip of the nose in comparison to the result with scalpel excision and suturing or grafting In all probability, failure to remove these nevi would result in no harm to the patient However, if the junction nevus shows activity in the form of growth or darkening of color, excision is advisable Certainly, neither lesion described in the question would seem to be in areas subjected to excessive trauma It must be emphasized that incomplete removal, with too much attention paid to cosmetic considerations, would be more dangerous than therapeutic inactivity

Melanomas may metastasize widely before there is clinical or histological evidence of malignant activity in the supposed primary lesion However, there are certain reservations to the glib acceptance of these cases as being proved Unless serial sections are studied, one might miss microscopic changes of malignant activity that could be overlooked in sections taken haphazardly from different levels of the block Secondly, even a postmortem study might fail to uncover a primary malignant melanoma in some other part of the skin, central nervous system, eye, or mucous membranes Therefore, one can understand that the removal of a nevus considered to be benign on histopathological examination does not preclude the possibility of a focus of malignancy somewhere in that neoplasm nor that the patient may not have a comparatively hidden primary melanoma elsewhere in his body As stated previously, ordinary blue nevi are benign and do not metastasize The cellular blue nevus of Allen may metastasize to lymph nodes, but this is a different tumor from the true blue nevus

ANSWER.—A pinhead-sized area of pigmentation remaining unchanged for a period of one year is not at all characteristic of a true pigmented nevus. In a woman of 50 years of age, it is much more likely that what is described is a very minute area of early senile lentigo or freckle. The true nevus is not ordinarily of this dimension. It is hardly likely that upon pathological examination neval cells will be found. The blue nevus is ordinarily the pigmented (Jadassohn-Tierche) type of nevus. This is almost always a benign growth.

NOCTURNAL PAIN WITH RHEUMATIC FEVER

To THE EDITOR.—*A 21-year-old man has a history of six episodes of acute rheumatic fever between the ages of 11 and 19. The physical, x-ray, and fluoroscopic examinations reveal that the patient has a combined mitral and aortic lesion and that the lesion in both valves is predominently one of insufficiency. His heart is very enlarged, especially on the right side. The cardiac rhythm and rate are normal, and the aorta is relatively small. Blood pressure in the right arm is 172/0 mm. Hg. His lungs are clear, but his liver is enlarged about three fingerbreadths below the costal margin and is slightly tender. At the present time the patient's chief complaint is that he gets a sharp pain just under the xiphoid process almost regularly at midnight and only sometimes during the day. This pain lasts about one and one-half to two hours and is not associated with eating. He has no cough, hemoptysis, or edema. What is the possible cause of 'midnight pain' in this patient, and what therapy would bring relief? Antispasmodics and sedatives, such as Belladenal Spacetabs, Dactil, Tridal, and Spastosed, do not help too much. A consultant feels that, because of severe involvement of mitral and aortic valves, this patient is not a suitable candidate for surgical treatment with the techniques presently available.*

Juliann Movchan, M.D., Oakwood, Ohio.

This inquiry has been referred to two consultants, whose respective replies follow.—ED.

ANSWER.—It is inferred from the query that the subxiphoidal distress of which the patient complains is causally related to assumption of the recumbent posture. It would be interesting to know what precipitating factors seem to be operative when similar, but apparently much less frequent and milder, discomfort occurs during the day, e.g., changes in body position, exertion, or emotional stress. Possible causes of this symptom are (1) increased liver engorgement producing, especially when the patient is in the decubitus position, unusual traction on the xiphosternal ligaments and/or diaphragmatic attachments, (2) atypical angina pectoris due either to a reduction of the cardiac output with a resulting diminution of coronary blood flow or to increased pulmonary congestion and pressure secondary to an augmented pulmonary blood volume during recumbency (the pain in the latter situation, however, would be much more apt to be midsubsternal or located diffusely over the anterior chest), (3) increased right ventricular volume, secondary to increased venous return, resulting in more traction on the xiphosternal ligaments, and (4) diaphragmatic hernia.

If hiatal hernia has been ruled out, such measures as the use of digitalis, diuretics, and Decholin ought seriously to be considered. If the employment of these agents in adequate amounts has no beneficial effect, long-acting vasodilators, such as some of the newer forms of nitroglycerine, choline theophyllinate, and pentaerythritol tetranitrate, might be given a trial.

ANSWER.—In all probability, this 21-year-old man will never be a candidate for corrective surgery. The recurrent episodes of acute rheumatic fever, the last occurring two years ago, and the findings of far-advanced valvular heart disease pose a complex problem. Disregarding the technical aspects of improving the combined aortic and mitral insufficiency, it would seem quite likely that this patient has active myocardial disease as well. The likelihood of active rheumatic myocarditis is in itself a strong deterrent to elective cardiac surgery, even though the valvular disease may be amenable to corrective surgery.

Nocturnal pain is not uncommon in young patients with severe aortic insufficiency. This is in sharp contrast to the exertional type of angina associated with aortic stenosis. This fact has been recognized for some time and is looked upon as an ominous finding from the standpoint of the patient's longevity. This pain is thought to be anginal in nature, although its nocturnal occurrence is not understood. Medical therapy is often unsatisfactory, but it would nevertheless seem advisable to try the medicaments usually employed for angina pectoris. Young adults who have a history of recurrent episodes of acute rheumatic fever and who present multivalvular lesions constitute real problems in therapy. Surgical intervention is rewarded only in those cases in which the rheumatic myocarditis has subsided. This would seem quite unlikely when there are persistent congestive manifestations and when nocturnal pain becomes a clinical feature.

SATURATED AND UNSATURATED FATS

To THE EDITOR.—*Some very interesting reports have appeared on cholesterol and saturated and unsaturated fats. Are there any unsaturated oils on the market?*

M.D., Minnesota.

ANSWER.—Evidence is accumulating that one of the factors influencing blood cholesterol is the type of fat in the diet. Scientists are currently working on the relative importance of blood cholesterol and the amount and kind of fat in the diet in relation to coronary heart disease. However, it is certainly premature to suggest that all saturated fats be eliminated from the diet, even if this were possible. The common sources of saturated fats are hydrogenated shortenings, butter, lard, and animal fat. The common sources of unsaturated fats are corn oil, cottonseed oil, peanut oil, and certain fish oils.

TREATMENT OF TETANUS

To the Editor.—*What is the correct method to treat tetanus in the following cases? 1. A boy, aged 10 years, weight 90 lb. (40.8 kg.), received an injury out of doors from a pointed stick. The wound, which was 0.5 in. deep and 0.5 in. long, was explored and disinfected. He was given 1,500 units of tetanus antitoxin and 600,000 units of penicillin. Penicillin was given daily or every other day for 12 days. Ten days after the injury he developed mild trismus. The next day the trismus was more marked and mild opisthotonos was present. The family thought that he had had all immunizations as a baby and a booster at the age of 5 and that he had had "a shot" after an injury in 1955. 2. Another patient had injections but is not sure what they were after injuries he received 10 years ago. There is no way of finding out definitely. There is no history of known active immunization. He now has an injury where tetanus may develop. 3. The last patient is known to have received tetanus toxoid 12 years ago and again 6 years ago. The first time, he received a series of active immunization doses. He now has an injury in which tetanus may develop. In any patient, is opening the wound at the time of onset of tetanus advisable, and, if so, to what extent?*

M.D., Michigan.

Answer.—In reference to the first case, in which tetanus did develop, the following statements are pertinent. First, a dose of 1,500 units of tetanus antitoxin is inadequate. The literature contains numerous references to failures in prophylaxis attending the prompt administration of this amount of antitoxin. Recommendations for minimal doses of 5,000 to 10,000 units for prophylaxis may be found in medical literature. Second, parenteral administration of penicillin in adequate recommended dosage is not reliable in the prevention of tetanus. Experiments purporting to support its prophylactic action refer to its local implantation in wounds at the time of infection, and the prophylactic effects under such conditions are far from reliable (experimental studies in animals). Third, the history is vague and makes no reference to validation concerning the time of injections or verification of the contents of the inoculations. Considerable risk is entailed in acceptance of hearsay evidence concerning immunization with tetanus toxoid. In the absence of a reliable history of toxoid inoculation, complete reliance must be based on prophylaxis with adequate amounts of potent antitetanic serum in proper doses.

In reference to the second patient, the following meaningful problem exists. The nature of the injections following trauma 10 years ago is not known. Only one injection, without a background of a reliable history of administration of tetanus toxoid in either civilian or military practice, would suggest the previous employment of tetanus antitoxin, probably of equine origin. Consequently, the presence of an injury of potential tetanogenic character would validate the use of tetanus antitoxin. To achieve this purpose, an elaborately cautious approach is indicated in order to avoid both morbidity and mortality from acute anaphylactic shock secondary to previous allergic sensitization. A detailed program applicable to this purpose is contained in an article by Spaeth (*Nebraska M. J.* 41:224, 1956).

In reference to the third patient, the following information may be applied. First, a booster injection of tetanus toxoid may be relied on as long as 10 or more years after basic immunization. In the case cited, a booster injection was given six years ago. Hence, in general, a booster injection of about 0.1 cc. of fluid tetanus toxoid, injected deep subcutaneously, is reliable prophylaxis. For general purposes, however, in order to allow for errors in measurement and administration, a dose of 0.5 cc. should be recommended. Herein lies a differentiation between the immunologically effective and the clinically reliable amount recommended. The latter accepts the element of human fallibility under average circumstances. Second, when a delay of one or more days between injury and prophylaxis supervenes, or when a quite extensive injury possibly conducive to a short incubation period is encountered, the additive security of combined toxoid-antitoxin prophylaxis may be entertained. In other words, toxoid and antitoxin may be employed. This principle applies only when the patient has had toxoid in the past. If toxoid, in adequate amount, has not been given previously, only antitoxin is to be employed.

Exploration and disinfection of wounds is an accepted procedure in prophylaxis, provided disfigurement is not entailed. The recommendations for treatment of wounds are no different for the prevention of tetanus than for the prevention of other complications of penetrating trauma. Obviously, nonmutilating removal of foreign bodies is indicated under proper circumstances. However, local procedures should be supplemented with specific prophylactic measures, i. e., administration of tetanus antitoxin or tetanus toxoid, individually or combined, as indicated by the attending circumstances. Opening of the wound at the onset of tetanus is justified only if the wound would require surgical treatment in the absence of tetanus. In other words, general surgical principles apply. Experimental evidence indicates that surgical treatment of the local lesion does not influence the course of clinically established tetanus.

HYPERCHOLESTEREMIA

To the Editor.—*In a patient with a blood cholesterol range of 250 to 275 mg. per 100 cc., would the use of Cytellin or nicotinic acid have virtue for cholesterol control?* *M.D., New York.*

Answer.—The Journal previously published a statement of the Council on Pharmacy and Chemistry on hypercholesteremia and atherosclerosis and a monograph on the mixture of sitosterols marketed under the trade name, Cytellin (*J. A. M. A.* 160:670-671 [Feb. 25] 1956). Cytellin may be tried as a means of reducing the level of blood cholesterol, although the evidence so far indicates that this is considered an experimental form of therapy. There is no evidence to indicate that nicotinic acid would be useful to control the level of blood cholesterol.

RESEARCH REVIEWS

From time to time there will be published in this section of THE JOURNAL *brief but not necessarily complete reviews of some of the newer clinical aspects of medical research and practice. This material is gathered specifically for* THE JOURNAL.—ED.

HEPATITIS

The sixth international symposium sponsored by the Henry Ford Hospital in Detroit was held in October, 1956. The title was "Hepatitis Frontiers." The full text of the papers and the discussions following them will be published in book form.[1] This is a brief summary of some of the topics discussed.

It is now thought, although not by all workers in this field, that two forms of viral hepatitis, infectious hepatitis and serum hepatitis, are caused by different viruses. It has been reported that the incubation period of infectious hepatitis is 15 to 40 days and of serum hepatitis, 60 to 160 days.[2] The virus that is thought to cause infectious hepatitis is referred to as virus A (I. H.) and the virus thought to cause serum hepatitis is referred to as virus B (S. H.). According to W. P. Havens Jr.,[1] Jefferson Medical College, Philadelphia, it is at present not certain whether the immunologic difference between virus A and virus B is representative of different viruses or of various strains of a single virus with antigenic differences potentiated by as yet undefined influences. He poses the question whether the family that goes to make up virus B may represent variants of virus A. I. W. McLean,[1] Detroit, reported the successful passage of agents derived from human sources.

The incidence of serum hepatitis after the use of human blood or some of its fractions has at times been considerable. Of particular importance has been the recognition of outbreaks in clinics where incompletely sterilized instruments were used in medical and dental work and where the chances of contaminations by carriers of virus were frequent.

The epidemiology of hepatitis was discussed by J. R. Paul,[1] Yale University, New Haven, Conn. J. L. Melnick,[1] of the same university, described an explosive epidemic in India and presented evidence, obtained mostly by Indian scientists, that it was water-borne. Sven Gard,[1] Karolinska Institute, Stockholm, traced an epidemic of some 600 cases of infectious hepatitis to oysters. R. L. Gauld,[1] Walter Reed Army Institute of Research, Washington, D. C., pointed to the relatively minor role played by food and water in the dissemination of the causal agents of hepatitis in the armed forces. He believes that the scattered cases of infectious hepatitis that occur in the military forces are transmitted by person-to-person contact.

To prevent serum hepatitis, practical means of sterilizing blood have been studied. F. W. Hartman,[1] G. A. LoGrippo,[1] and A. R. Kelly,[1] Henry Ford Hospital, consider beta-propiolactone a potentially useful agent for this purpose. They believe that its action is virucidal. They are now investigating whether beta-propiolactone in a concentration sufficient to sterilize whole blood may be used without deleterious effects on erythrocytes. They hold that it has many properties that make it suitable for the sterilization of plasma. They have used it to sterilize arterial homografts and bone transplants, and they have kept packaged meat preserved by a 1% solution of beta-propiolactone for one week at room temperature without mold formation.

According to these workers,[3] beta-propiolactone can be used in the preparation of vaccines in a concentration in excess of the minimal effective virucidal dose with a wide margin of safety between the complete inactivation of virus and the loss of antigenicity. It is thought to be superior to other chemical agents in the preparation of virus-inactivated vaccines and is reported to inactivate viruses completely in 10 to 15 minutes at 37 C. Its virucidal action is said to be almost instantaneous, and viruses are inactivated before beta-propiolactone undergoes complete hydrolysis. It is stable in the absence of moisture and rapidly disintegrates in aqueous solution into nontoxic products chemically related to lactic acid. During the past five years, 414 patients in Detroit[1] received 1,153 transfusions with a total of 290 liters of beta-propiolactone–treated plasma. There were no cases of serum hepatitis following these transfusions, and there was no evidence of either acute or chronic toxic effect.

Undegraded beta-propiolactone has been studied experimentally as a carcinogenic agent.[4] The conclusion reached is that there seems to be no contraindication to its use in the sterilization of blood or plasma for transfusion because of its rapid and complete disintegration into other compounds.

According to R. Murray,[5] National Institutes of Health, Bethesda, Md., it is very difficult to destroy the agent of serum hepatitis by any means; he has been unable to do so with beta-propiolactone in a concentration of 3,500 mg. per liter. This was demonstrated in human volunteers. To reduce the quantity of beta-propiolactone necessary for the complete sterilization of biological fluids, the concomitant use of ultraviolet irradiation has been discussed at various times.[6] R. T. Jordan and L. N. Kempe,[7] City of Hope Medical Research Institute, Duarte, Calif., and University of Michigan, Ann Arbor, have attempted sterilization by gamma radiation from radioactive cobalt, and J. G. Trump,[1] Massachusetts Institute of Technology, Boston, by high-energy electrons. The storage of pooled plasma at room temperature as a means of preventing viral hepatitis has been reported by G Allen,[1] University of Chicago

R F Norris,[1] University of Pennsylvania, Philadelphia, discussed the problem of detecting asymptomatic carriers of viral hepatitis in the selection of blood donors Although, in his opinion, hepatic function tests used thus far do not appear to be specific for liver disease or viral hepatitis, he believes that a significant number of asymptomatic carriers of viral hepatitis can be detected by employing these tests in screening He said that measurement of serum transaminase activity may also be useful in a screening program

In the discussion of laboratory methods in differential diagnosis, F Wróblewski,[1] Memorial Center for Cancer and Allied Diseases, New York, referred to measurements of glutamic oxaloacetic transaminase and glutamic pyruvic transaminase He showed that, in acute infectious and in serum hepatitis, there is an increase in both these enzymes in the serum He said that there seems to be a close relation between the level of these serum transaminases and the clinical state of the patient, with levels reaching a peak of 10 to 100 times the normal at the time when fever, malaise, anorexia, nausea, vomiting, and hepatic tenderness are at their height With subjective and objective improvement, there is a concomitant fall in the level of both serum transaminases In a paper to be published,[7] he and his colleagues claim that elevations in the serum level of transaminases reflect subclinical hepatitis more sensitively than the conventional liver-function tests

H Ducci,[1] Santiago, Chile, referred to the use of serum aldolase and serum iron determination in the differentiation between acute and chronic types of liver disease with jaundice He had found that patients with hepatitis showed high aldolase and serum iron values In acute hepatitis, aldolase and bilirubin followed a parallel course, reaching normal values almost simultaneously, while the serum iron level remained elevated for a longer period R Ward,[1] New York University College of Medicine, New York, said that the serum phosphohexose isomerase test developed by Bodansky was useful in the detection of the disease in children before symptoms developed

H L Bockus,[1] University of Pennsylvania, Philadelphia, as moderator of the round-table discussion on differential diagnosis of hepatitis, suggested that the galactose test should not be discarded and should be used in conjunction with the other tests now in favor G Viollier,[1] Basel, Switzerland, showed how electrophoretic blood protein patterns may be used in the differential diagnosis of liver disease He thought that, while the changes in the blood protein patterns are not specific for liver disease, they permit conclusions as to diagnosis and prognosis

J L Bollman,[1] Mayo Clinic, Rochester, Minn, said that there are now three biliary pigments known Pigments I and II give a direct van den Bergh reaction, they are excreted in the bile and may be excreted in the urine He believes that pigment I and bilirubin are formed outside the liver and that conversion of these two pigments to pigment II occurs only in the liver In animals, pigment II predominated in the blood after uncomplicated obstruction of the common bile duct, which was taken to indicate that pigment I and bilirubin continued to be converted to pigment II With continued biliary obstruction, larger amounts of pigment I appeared in the blood In 50 patients with hepatocellular disease or obstructive jaundice, partition of the three bile pigments of their serums appeared to indicate that retention of a large portion of pigment I was associated with hepatocellular disease and that larger amounts of pigment II were retained when biliary obstruction was present

Observations on bilirubin-protein linkages in serum and their relation to the van den Bergh reaction have been made by G Klatskin,[8] Yale University, who has reported that the bulk of bilirubin in serum is bound to albumin, irrespective of its behavior in the van den Bergh reaction He believes that there is no evidence that, in the breakdown of hemoglobin, globin remains attached to its prosthetic group to yield indirect-reacting bilirubin and that the two types of van den Bergh reaction are not related to differences in bilirubin-protein linkages

HALF A BILLION DOLLARS ASKED FOR CANCER RESEARCH

The Senate appropriations subcommittee closed extensive hearings on the Health, Education, and Welfare budget after hearing more than a hundred witnesses urge continued or increased spending in the health-welfare fields One of the last witnesses was Senator Neuberger (D , Ore), who asked that the HEW budget for the next fiscal year be sharply increased for cancer research

The Oregon senator, along with Senator Morse (D , Ore), has introduced an amendment to the HEW appropriation bill that would provide 500 million dollars for the National Cancer Institute, to be used for arriving at a cure for cancer Unlike a regular appropriation, which must be spent or committed during the fiscal year, funds under the Neuberger-Morse amendment could be used until totally expended

Senator Neuberger emphasized to the appropriations group headed by Senator Hill (D , Ala) that cancer should be attacked along the same line as the U S development of atomic and intercontinental ballistic weapons The administration asked Congress in January for $46,902,000 for the Cancer Institute for the 12 months starting July 1 The House agreed with this figure, and the matter is still before the Hill subcommittee

The subcommittee heard additional pleas for allowing 25% for overhead costs to institutions and medical schools getting federal research money The House last year set a 15% limit, which has produced objections both in and out of government Among those asking for a higher percentage were Drs Isador Ravdin, University of Pennsylvania Medical School, Harold Diehl, University of Minnesota Medical School, Irving Wright, Cornell University Medical School, Cowles Andrus, John Hopkins University Medical School, and Sidney Farber, Children s Hospital, Boston

Other physicians testifying in support of health items were Drs John H Talbott, University of Buffalo Medical School, Rene Dubos, Rockefeller Institute, Walsh McDermott, Cornell University Medical School, Alson Braley, Iowa School of Medicine, Arthur Colwell, Northwestern University School of Medicine, and H Houston Merritt, New York Neurological Institute

Organizations represented at the hearings and urging approval of research funds already voted by the House included the American Cancer Society, the National Committee Against Mental Illness, the Arthritis and Rheumatism Foundation, and the National Committee for Research in Neurological Disorders This last group is made up of nine organizations such as United Cerebral Palsy, Muscular Dystrophy Association, National Association of Crippled Children and Adults, and National Epilepsy League

Other budget developments in the closing days of the hearings were as follows

A witness for the AFL-CIO generally urged increases all along the line, and, supporting federal construction aid to medical and dental schools, described this as "perhaps the most seriously neglected area of all in the entire health field '

Social Security Commissioner Schottland said there were few agencies of government that have had "legislative changes which resulted in such substantial program and work load expansions as we have within the last year " Included in this category are the disability cash payments which will start going out July 1 to disabled workers 50 years or older whose claims have been processed and allowed Mr Schottland estimated that during the present fiscal year more than 10 million individuals will receive Old-Age and Survivors Insurance payments, a total in excess of 6 billion dollars

Col Frank B Rogers, director of the National Library of Medicine, declared that no other medical agency of the federal government "serves the future of medical research more intimately and more widely than does the unequaled collection of books, journals, and bibliographic services brought together in the National Library of Medicine ' The library is under the supervision of the Public Health Service

NURSING HOMES GET FEDERAL AID

Three nursing homes and a hospital have recently received loans for expansion of facilities under the Small Business Administration program The agency lends money to various small businesses when local financing is not available on reasonable terms SBA loan operations have been curtailed since February because of near exhausation of its revolving fund, but recent deficiency appropriation of 45 million dollars has put the SBA back in business

The SBA listed these loans to health facilities Hocott Memorial Home, Little Rock, Ark , $50,000, Farragut Nursing Home, Brooklyn, N Y , $50,000, Buffalo Hospital, Buffalo, Okla , $33,000, Alondra Nursing Home, Gardena, Calif , $87,000

HEALTH INSURANCE ASSOCIATION MEETING

Progress and problems in the health insurance field were discussed at the annual meeting of the Health Insurance Association of America The 450 delegates, representing 256 companies, also heard A M A President-elect David B Allman outline the physician's concern with the financing of medical service and Secretary Folsom explain why the administration wanted Congress to pass a bill for construction aid to medical schools

---

From the Washington Office of the American Medical Association

Appearing on a panel, Dr. Allman told the insurance people:

"I am . . . convinced . . . that your industry must step up markedly your program of physician-relations. You cannot expect physicians to understand fully the relation between fees and the salability of major medical insurance . . . you must discuss frankly with practicing physicians and their local medical societies the needs and objectives of this type of insurance. Such a program of professional relations takes money and personnel but I urge you to undertake it."

Dr. Allman said the medical profession wants a price for its services that can be met by the public "through mechanisms that do not adversely affect the quality of care rendered," but that any mechanism that is a step toward socialization must be opposed. He said the physicians will expect adequate compensation, but that they will question the provision of care by closed panels. Also, Dr. Allman declared, doctors will oppose government financing of medical costs "that are properly and more wisely the obligation and responsibility of individuals."

In summary, he said:

"The physician will support or oppose any program for the financing of health care costs depending on the effect of that program on the quality of the service the physician renders. So long as the insurance you promote is consistent with the maintenance of high quality medical care you can be assured that medicine will support you."

After discussing the national interest in medical research, Mr. Folsom said it was also necessary to increase the supply of medical scientists trained in research.

"Unless we have the facilities to teach the number of scientists and physicians we need," he stated, "our medical progress in the future could be seriously retarted. Therefore, we have appealed to Congress to expand this legislation to include help in the construction of medical teaching facilities."

He described the administration's aid to medical education bill as "a sound, prudent, and profitable investment in the future health of the American people."

CONGRESS RECEIVES MESSAGES ON JENKINS-KEOGH

Members of the House and Senate have received "thousands of messages" urging passage of the Jenkins-Keogh retirement legislation, Rep. Thomas Jenkins (R., Ohio) declared in a speech explaining the proposal to the House.

"I am sure that practically all members have been receiving messages of some kind with reference to the Jenkins-Keogh bill," he said. "As proof that it is a good bill, on yesterday I received 300 telegrams in favor of the bill, so it seems to be very popular. These telegrams were signed by doctors, lawyers, influential businessmen. The measure now is before the House Ways and Means Committee.

"I am advised," he continued, "that membership of the House and Senate have received thousands of messages, most from business and professional men and women." In an analysis of the legislation, Mr. Jenkins made these points:

1. It would allow the self-employed to defer income taxes on a portion of their income if put into a restricted annuity plan.

2. Actual annual deductions could not exceed 10% of self-employment income, or $5,000, whichever is the lesser. However, for persons now 50 years of age or over, deductions could be increased 1% a year between ages 50 and 70. Deductions over a lifetime could not exceed 20 times the maximum annual deduction.

3. The definition of self-employed would be the same as that used for Social Security, except that persons not covered by Social Security also would be eligible under this pension plan.

4. Funds could be invested only in federal, state, and municipal securities, corporate stock, or securities listed on a recognized exchange. Approved retirement policies also would include life insurance or annuity contracts, except that the cost of life insurance protection could not be deducted.

5. Generally, retirement funds would not be payable until age 65, at which time they would be subject to payment of income tax by the recipients; money could be withdrawn earlier, but only on payment of a tax penalty.

INTERNATIONAL CONGRESS OF OTOLARYNGOLOGY

For a full week, 1,600 otolaryngologists from 48 countries all over the world met together in Washington to exchange ideas. The meeting was the sixth International Congress of Otolaryngology, and the first such session held in the United States. It was sponsored by the five American societies of otolaryngology.

Principal subjects discussed were chronic suppuration of the temporal bone, collagen disorders of the respiratory tract, and papilloma of the larynx. Approximately 250 voluntary scientific contributions were made available in the form of papers or lectures, and 65 medical motion pictures were shown. The latest advances in otolaryngology were shown in scientific exhibits and color television.

Vice-president Nixon, one of the guest speakers, complimented the physicians on their international cooperation and said the world would be better off if politicians could develop the same type of cooperation. He paid particular tribute to those physicians who speak "many languages." Official languages of the congress were English, French, and German.

COMMITTEE NAMED TO STUDY INDIAN'S NUTRITIONAL PROBLEMS

To help it determine the extent to which faulty nutrition is the cause of Indian health problems, the Public Health Service has appointed a consultant committee composed of professional leaders from the fields of medicine and nutrition.

The committee, which held its organization meeting April 29, will determine priorities for nutrition research and the most suitable methods of investigation. Also, acting for the PHS, it will review nutrition research projects involving Indians which are proposed by individuals and institutions.

Members of the committee, which will meet twice a year, are Dr. William J. Darby, Vanderbilt University; Dr. Olaf Michelsen, National Institutes of Health; Dr. John Adair, Cornell University; Miss Marjorie Heseltine, U. S. Children's Bureau; Dr. Robert E. Shank, Washington University School of Medicine, St. Louis, Mo.; Dr. Charlotte Young, Cornell University, and Dr. Luther L. Terry, National Heart Institute.

"For prompt relief [of nausea during pregnancy] the use of Dramamine is recommended (50 mg. twice daily tapering off rapidly to use only as required)."

Gods—Saints and Pestilences

In the pantheon of ancient Greece, Apollo, the Far-Darter, was the god who flung the arrows of pestilence among humanity, and in the first book of the Iliad, Homer makes Chryses, a priest of Apollo, call upon the god to send a plague among the Greeks because Agamemnon had refused to restore the captive daughter of Chryses to her father He was also, as Homer relates, the physician to the Olympian gods, whose wounds or diseases he cured by means of the root of the peony Apollo, therefore originally occupied a dual role in the Greek pantheon—he was at once the celestial sower of pestilence and the chief god of healing Later the Greeks, to obviate this antithesis, decided to confine Apollo s activities to the dissemination of pestilences They accordingly discovered Æsculapius and invested him with such marvellous powers of healing that Pindar said that Pluto persuaded Zeus to destroy him because he had so much reduced the number of shades in Hades After his death he was elevated to the Greek pantheon as the God of Healing and his cult became widespread throughout the Ancient Greek and Roman worlds

Since the death of Jesus Christ, Christendom has repeatedly been scourged, and sometimes devastated, by epidemics of disease Christian societies attributed these visitations to the righteous wrath of God who had sent his Angel of the Pestilence down from Heaven to Earth to punish humanity for its sins The mediaeval conception of the origin of pestilential disease is clearly expressed in Delaunay s beautiful representation of the Plague of Rome In this painting he depicts the Angel of the Lord as pointing out to the Spirit of the Pestilence the homes of those who have been selected to experience the divine punishment

One of the earliest and most venerated of the Christian saints who were specifically invoked in times of pestilence was St Sebastian About A D 283, according to Butler he voluntarily entered the Roman army in order to be able to help the Christian martyrs without arousing suspicion Apparently he early won the favourable notice of the emperor, Diocletian, who, ignorant of his religious beliefs, promoted Sebastian to be a company commander in the Praetorian Guards In A D 286 however, he was betrayed to Diocletian According to the legend, he was first condemned to be fastened to a stake and shot to death by arrows—note the introduction of the arrow, or dart, motif in connexion with a patron saint of pestilence—and when his body was studded with arrows his executioners quite reasonably left him for dead That night, however, Irene the widow of his martyred friend, St Castulus, coming to collect the body for Christian burial, found that Sebastian was still alive and managed to nurse him back to health After he had regained his health Sebastian deliberately accosted Diocletian in public and denounced his abominable cruelties to the Christians, with the result that the emperor had him beaten to death with clubs

The earliest representation of St Sebastian in Christian art appears to be the ancient mosaic in the church of San Pietro in Vincoli, which was supposedly executed in A D 683, and which depicts him as a bearded soldier, in Roman dress, wearing a cuirass and toga On a marble table at one side of this mosaic there is a Latin inscription which reads in English 'To St Sebastian Martyr, dispeller of the pestilence In the year of salvation, 680, a pernicious and severe pestilence invaded the city of Rome It was of three months duration, July, August and September Such was the multitude of the dead, that, on the same bier, parents and children, husbands and wives, with brothers and sisters were borne out to burial places, which everywhere filled with bodies, hardly sufficed In addition to this, nocturnal miracles alarmed them, for two angels, one good and the other evil, went through the city, and this last bearing a rod in his hand, as many times as he struck the doors so many mortals fell in those houses' (It was this pestilence and this legend that provided Delaunay with the subject for his painting)

St Sebastian was one of the most popular saints in mediaeval art, and there are many paintings of him, most of which depict him in the first stage of his martyrdom A most interesting feature of his treatment in mediaeval art is the gradual transformation that he undergoes, during the passage of the centuries, from the bearded Roman soldier, probably a man approaching early middle age, to the radiant, god like youth, the Christian equivalent of the pagan Apollo The chief plague saint throughout Western Europe from the time of the Great Pestilence onwards was St Roch, who may have supplanted St Sebastian in that connexion—Prof J F D Shrewsbury, M D, The Saints and Epidemic Disease, *The Birmingham Medical Review* No 7-8, Winter, 1956

Bright and Early

They woke me up at half past five
To see if I was still alive

They came again at six o'clock
To see how I had stood the shock

At half past six they brought a basin
For me to wash my hands and face in

At seven o clock they came and said
We ve got to sweep beneath your bed

At half past seven they said to me
Perhaps you re ready now for tea

The doctor may be round at ten—
Don t disarrange your bed till then

ROLE OF THE COMMUNITY HOSPITAL IN CONTINUING EDUCATION—THE HUNTERDON EXPERIMENT

Edmund D Pellegrino, M D, Flemington, N J

• *For postgraduate medical education to be most effective, especially for the rural practitioner, it should be continuous and should be carried out in relation to individual patients in the community hospital. The community hospital must become an educational institution, with the local practitioner as a participant in an interchange of ideas between himself and the specialist. In one area, relatively devoid of industry, there has been a translation of the atmosphere and techniques of a university teaching hospital to a community rural medical center. This approach to continuing education should be translatable to other communities.*

The ideal of lifelong, continuing professional education has been axiomatic for the worthy physician in every age. Indeed, this is a moral and social responsibility that flows necessarily from the firm relationship that exists between the quality of medical care and the level of education of the physician. It applies with equal force to the teacher and the investigator and, perhaps with the greatest urgency, to the practicing clinician.

In the past 50 years, the range of knowledge in the sciences pertinent to medicine has been expanding at an exponential rate with the result that the realization of this ideal has become an enormous task even for the academic physician and the specialist. For the general practitioner, the problem is complicated by the exigencies of patient care as well as by the obvious restrictions imposed by time and by the limitations of the human intellect.

Physicians who do not have a direct relationship with a medical school or a university teaching hospital supply the greatest proportion of medical care in the United States today. Most of these men are general practitioners, and there is every indication that some type of general or family physician will continue to fulfill the medical needs of rural and semirural regions in the foreseeable future. Some method must be devised whereby this group of physicians may be enabled to improve their skills for the better service of the community and to experience the intellectual stimulation necessary for the continual acquisition of knowledge and understanding of recent advances.

The ever widening horizons of medical information and the changing role of the physician in modern society have produced such demands at the earlier levels of medical education that more of the detailed and specialized knowledge of medical practice must now be obtained in the postgraduate years.

Medical educators have been acutely aware of these problems, and a number of partially effective solutions have been devised. Postgraduate courses, seminars, symposiums, residencies, and scientific meetings have all been multiplied in recent years with the end in view of continuing the physician's education. These methods are reasonable and useful, but they are limited since they are elective and temporary stimulants intermittently applied and are attended by only a small percentage of practicing physicians. Rural practitioners often cannot leave their communities deprived of medical care for a long enough time to attend. These more or less formal methods are essentially didactic and, therefore, result in a passive rather than an active educational process.

Such techniques will continue to be of value, but what is needed more than their further multiplication is a reinculcation of the teaching atmosphere into the daily life of the individual practitioner. For postgraduate medical education to be most effective, it should be continuous and should be carried out in relation to individual patients in the community hospital. If the practicing physician could have informal and easily available guidance at all times at a level equivalent to that of a university hospital, he would be in the best position to improve the care of the patient in his own office, in the home, and in the hospital.

Medical Director and Director of Internal Medicine Hunterdon Medical Center, and Assistant Professor of Clinical Medicine New York University College of Medicine.

Read before the 53rd Annual Congress on Medical Education and Licensure, Chicago Feb 11 1957.

To achieve this, the community hospital would have to become an educational institution in the true sense, a place where an interchange of ideas and experiences can occur between specialist and general practitioner and house staff and where clinical, bedside, and laboratory teaching can become a routine experience If, instead of being isolated from such an atmosphere, the practitioner can be made a participant, the community hospital could provide at least a setting for the pursuit of the ideal of lifelong professional medical education

Description of Hunterdon Program

I would like to describe the experiences of one rural community medical center that has attempted to actualize these concepts in its medical program during the past four years Emphasis will be given to the question of continuing education of general practitioners, although the process necessarily involves the house staff, the medical student, and the specialist

The Hunterdon Medical Center in Flemington, N J, is a 120-bed voluntary general hospital serving a semirural population of about 45,000 persons It is situated midway between New York and Philadelphia in an area, relatively devoid of large industries, deriving its income from poultry and dairy farming and light industry The medical center arose out of the community's basic need for hospital services, since Hunterdon County was previously devoid of such facilities and its general practitioners depended upon adjacent communities for hospital and specialist care

From its inception, the institution has enjoyed a unique history of cooperation between the community and the professional organizations inspired by farsighted local lay leadership An account of the center's genesis and development has been published in monograph form,[1] and this monograph should be referred to for many of the background details that I am not including in this report Some seven years were spent by community leaders in collaboration with the late Dr H L Corwin of the New York Academy of Medicine and with representatives of New York University and the Commonwealth Fund in elaborating the philosophy of medical care that will be described Financial assistance in the form of grants was made possible by the Commonwealth Fund, the Kress Foundation, and the New Jersey State Department of Health The local general practitioners were consulted early and gave their approval to the over-all philosophy several years before any specialists were engaged

Objectives of Program —The objective of the center, briefly stated, is to provide a broad spectrum of modern medical services to a rural community at a level of quality equivalent to that practiced in the university medical centers The distinguishing features of this program can only be enumerated here and are as follows (1) a rural medical center that would provide the widest range of health services—diagnostic, therapeutic, preventive, and rehabilitational, (2) a staff that would make available to the patient the services of both family physicians and specialists working in a cooperative relationship, (3) an intimate association with a university medical school so that teaching and research could be combined with community service for the continuing education of the general practitioner and the betterment of medical care, (4) a group of "geographical" full-time specialists who would confine their practice to the medical center and pool their financial resources, and (5) a plan that would be economically feasible and supportable by local funds

The most crucial, professional aspect of the Hunterdon experiment is the acceptance as a central principle that the optimum care of patients in a rural area can best be achieved by a cooperative effort between the general physician and the specialist It is recognized that each has a unique contribution to make and that the betterment of medical care pivots on the existence of a satisfactory modus vivendi between these groups

Present Operation —The staff at the present time consists of 15 full-time, salaried specialists and 35 general practitioners, who are the family physicians of the community Most of the general practitioners were in practice locally before the inception of the center In addition, there is a part-time specialist staff consisting of 20 men in most of the medical and surgical subspecialties

The full-time specialist staff consists of three internists, two general surgeons, an orthopedic surgeon, pediatrician, gynecologist and obstetrician, otorhinolaryngologist, ophthalmologist, pathologist, psychiatrist, anesthesiologist, urologist, and radiologist Each of these men serves as the director of his respective service, carries out a consultation practice in the diagnostic center, and is charged by the board of trustees with the responsibility of maintaining university standards of medical care in his department The members of the specialist staff do not practice outside the center, they see outpatients on referral from the general practitioner, and they do not make house calls except on his request They are paid by fees received for their professional services and do not receive any support from nonprofessional sources such as income from the hospital for room and board They pool their fees in a professional service fund from which each full-time member receives a salary that is dependent upon his professional rank and not on the type of specialty in which he is engaged This fund cannot be used for nonprofessional purposes

Every general practitioner in good standing in the county medical society may become, and, indeed, has become, a member of the attending staff of the Hunterdon Medical Center The general practitioner is a co-member with the specialist in all activities of the hospital There is no general practice department because it is felt that the organizational philosophy is such that the prerogatives and privileges of the general practitioner can be served without such a department Indeed, he has an equal representation with the specialist in every aspect of the hospital's function, administrative and clinical, so that he enjoys a genuine sense of participation

The general practitioner has privileges on all the major clinical services as determined by the medical board, which is made up of both general practitioners and specialists in equal numbers The general practitioner does not perform major surgery, but rather he concentrates on medicine, pediatrics, normal obstetrics, and minor surgery He may admit patients to any service, and, when he does, he is expected to carry out the traditional duties of the attending physician

Association with Other Institutions.—The Hunterdon Medical Center is a teaching hospital in every sense of the word It is a member of the regional hospital plan of New York University-Bellevue Medical Center and a member of the university's administrative staff sits on the medical board Each of the full-time specialists is a faculty member at New York University so that, in essence, there is available a local full-time teaching staff in the community hospital itself Each full-time man spends one day a week in his respective department at New York University throughout the academic year carrying out a teaching responsibility, attending conferences, and keeping himself abreast of advances in his own field The medical center has a house staff consisting of nine general practice and specialty residents and interns who are rotated from other affiliated hospitals of New York University In addition, there are five to six senior medical students from three schoools—New York University College of Medicine, the University of Pennsylvania School of Medicine, and State University of New York College of Medicine These students spend an elective period of from six weeks to three months at the center Every patient, regardless of economic classification or social status, is a teaching patient in the sense that he is examined and studies are made on him by members of the house staff and that he may be presented at conferences, his management may be reviewed, and he himself may be examined by the chief of the service

Routine on Various Services

Most of the teaching is carried out informally, often individually, and in close proximity to the bedside A clearer understanding of the manner in which this is accomplished and in which it can influence the care of the patient as well as fulfill a learning experience for the practitioner is best gained by a review of the routine employed on the medical and pediatric services

On these services, as on all the major services, each patient is considered to be the joint responsibility of the director of the service and the attending physician The types of patients may be divided generally into three broad categories, and the degree of supervision and guidance carried out by the chief of the service will depend upon the patient's classification Thus, about 50% of the patients have been hospitalized by the family doctor under his direct and immediate care Most of these are treated for the usual illnesses that are well within the ability of the family physician to handle, with occasional guidance and supplementation by the specialist Another 25% are referred directly to the care of a specialist either by virtue of the distance of the physician from the hospital or by reason of the complexity of the problem In these cases the specialist assumes the full role of management of the patient The general practitioner, nevertheless will usually see these patients several times a week and confer with the specialist about their management On discharge the patient is returned to his referring physician with a detailed summary of his hospital stay, together with specific recommendations regarding diagnosis and future management The last 25% of patients consists of those cases in which the family physician, although retaining the attending role, will need and request formal consultation by the specialist because of a difficult diagnostic or therapeutic problem

The director of the service makes rounds every day with his house staff and reviews in detail the studies made by the house staff and the attending physician He sees every patient regardless of who the attending physician may be, and, if necessary, he can take additional history from the patient and examine him He then confers routinely with the family physician concerned when the latter makes his own rounds In this way, the director of the service is able to supervise closely the general work of the service and can establish good standards of medical care with regard to diagnosis, management, and therapy Each patient and his physician, in effect, have informal, routine consultations When there are disagreements in management or diagnosis, these are discussed with the attending physician and not with the patient

The general practitioner on his part is expected to see his patient, write admission and progress notes, communicate his orders to the house staff, and keep himself informed on the patient's progress He carries the responsibility for admission and discharge and for communication with the family and patient regarding diagnosis, treatment, and so forth He bills the patient for his services in the usual manner There is no charge by the specialist for his over-all supervision but he does charge a fee in the usual manner for those patients directly under his care and for all formal consultations

Every effort is made to preserve the role of the family doctor as the attending physician The specialist staff firmly believes in the inviolability of this relationship No major change in management [illegible] by the house staff or the specialist without the [illegible] knowledge and consent of the family physician

On the surgical service the general [illegible] responsible for the preoperative [illegible] care of his patient and the management [illegible] medical problems He may assist [illegible] procedures The teaching emphasis [illegible] nosis the indications for operation [illegible] postoperative complications [illegible] cedures

Family physicians deliver 85% of the obstetric patients in this institution The obstetrician [illegible] is responsible for the establishment of standards of obstetric care He has a knowledge of all [illegible] performed, keeps careful check of the number and kind of services performed, and is available for all obstetric emergencies and complicated cases All the gynecologic surgery is performed by the full-time specialist The teaching technique is similar to that on the medical and pediatric services, and the emphasis is on prenatal and postpartum care, office practice of [illegible] and the physiology of normal labor

To achieve this, the community hospital would have to become an educational institution in the true sense, a place where an interchange of ideas and experiences can occur between specialist and general practitioner and house staff and where clinical, bedside, and laboratory teaching can become a routine experience If, instead of being isolated from such an atmosphere, the practitioner can be made a participant, the community hospital could provide at least a setting for the pursuit of the ideal of lifelong professional medical education

Description of Hunterdon Program

I would like to describe the experiences of one rural community medical center that has attempted to actualize these concepts in its medical program during the past four years Emphasis will be given to the question of continuing education of general practitioners, although the process necessarily involves the house staff, the medical student, and the specialist

The Hunterdon Medical Center in Flemington, N J, is a 120-bed voluntary general hospital serving a semirural population of about 45,000 persons It is situated midway between New York and Philadelphia in an area, relatively devoid of large industries, deriving its income from poultry and dairy farming and light industry The medical center arose out of the community's basic need for hospital services, since Hunterdon County was previously devoid of such facilities and its general practitioners depended upon adjacent communities for hospital and specialist care

From its inception, the institution has enjoyed a unique history of cooperation between the community and the professional organizations inspired by far-sighted local lay leadership An account of the center s genesis and development has been published in monograph form,[1] and this monograph should be referred to for many of the background details that I am not including in this report Some seven years were spent by community leaders in collaboration with the late Dr H L Corwin of the New York Academy of Medicine and with representatives of New York University and the Commonwealth Fund in elaborating the philosophy of medical care that will be described Financial assistance in the form of grants was made possible by the Commonwealth Fund, the Kress Foundation, and the New Jersey State Department of Health The local general practitioners were consulted early and gave their approval to the over-all philosophy several years before any specialists were engaged

Objectives of Program —The objective of the center, briefly stated, is to provide a broad spectrum of modern medical services to a rural community at a level of quality equivalent to that practiced in the university medical centers The distinguishing features of this program can only be enumerated here and are as follows (1) a rural medical center that would provide the widest range of health services—diagnostic, therapeutic, preventive, and rehabilitational, (2) a staff that would make available to the patient the services of both family physicians and specialists working in a cooperative relationship, (3) an intimate association with a university medical school so that teaching and research could be combined with community service for the continuing education of the general practitioner and the betterment of medical care, (4) a group of "geographical full-time specialists who would confine their practice to the medical center and pool their financial resources, and (5) a plan that would be economically feasible and supportable by local funds

The most crucial, professional aspect of the Hunterdon experiment is the acceptance as a central principle that the optimum care of patients in a rural area can best be achieved by a cooperative effort between the general physician and the specialist It is recognized that each has a unique contribution to make and that the betterment of medical care pivots on the existence of a satisfactory modus vivendi between these groups

Present Operation —The staff at the present time consists of 15 full-time, salaried specialists and 35 general practitioners, who are the family physicians of the community Most of the general practitioners were in practice locally before the inception of the center In addition, there is a part-time specialist staff consisting of 20 men in most of the medical and surgical subspecialties

The full-time specialist staff consists of three internists, two general surgeons, an orthopedic surgeon, pediatrician, gynecologist and obstetrician, otorhinolaryngologist, ophthalmologist, pathologist, psychiatrist, anesthesiologist, urologist, and radiologist Each of these men serves as the director of his respective service, carries out a consultation practice in the diagnostic center, and is charged by the board of trustees with the responsibility of maintaining university standards of medical care in his department The members of the specialist staff do not practice outside the center, they see outpatients on referral from the general practitioner, and they do not make house calls except on his request They are paid by fees received for their professional services and do not receive any support from nonprofessional sources such as income from the hospital for room and board They pool their fees in a professional service fund from which each full-time member receives a salary that is dependent upon his professional rank and not on the type of specialty in which he is engaged This fund cannot be used for nonprofessional purposes

Every general practitioner in good standing in the county medical society may become, and, indeed, has become, a member of the attending staff of the Hunterdon Medical Center The general practitioner is a co-member with the specialist in all activities of the hospital There is no general practice department because it is felt that the organizational philosophy is such that the prerogatives and privileges of the general practitioner can be served without such a department Indeed, he has an equal representation with the specialist in every aspect of the hospital's function, administrative and clinical, so that he enjoys a genuine sense of participation

The general practitioner has privileges on all the major clinical services as determined by the medical board, which is made up of both general practitioners and specialists in equal numbers. The general practitioner does not perform major surgery, but rather he concentrates on medicine, pediatrics, normal obstetrics, and minor surgery. He may admit patients to any service, and, when he does, he is expected to carry out the traditional duties of the attending physician.

Association with Other Institutions.—The Hunterdon Medical Center is a teaching hospital in every sense of the word. It is a member of the regional hospital plan of New York University-Bellevue Medical Center and a member of the university's administrative staff sits on the medical board. Each of the full-time specialists is a faculty member at New York University so that, in essence, there is available a local full-time teaching staff in the community hospital itself. Each full-time man spends one day a week in his respective department at New York University throughout the academic year carrying out a teaching responsibility, attending conferences, and keeping himself abreast of advances in his own field. The medical center has a house staff consisting of nine general practice and specialty residents and interns who are rotated from other affiliated hospitals of New York University. In addition, there are five to six senior medical students from three schoools—New York University College of Medicine, the University of Pennsylvania School of Medicine and State University of New York College of Medicine. These students spend an elective period of from six weeks to three months at the center. Every patient, regardless of economic classification or social status, is a teaching patient in the sense that he is examined and studies are made on him by members of the house staff and that he may be presented at conferences, his management may be reviewed, and he himself may be examined by the chief of the service.

Routine on Various Services

Most of the teaching is carried out informally, often individually, and in close proximity to the bedside. A clearer understanding of the manner in which this is accomplished and in which it can influence the care of the patient as well as fulfill a learning experience for the practitioner is best gained by a review of the routine employed on the medical and pediatric services.

On these services, as on all the major services, each patient is considered to be the joint responsibility of the director of the service and the attending physician. The types of patients may be divided generally into three broad categories, and the degree of supervision and guidance carried out by the chief of the service will depend upon the patient's classification. Thus about 50% of the patients have been hospitalized by the family doctor under his direct and immediate care. Most of these are treated for the usual illnesses that are well within the ability of the family physician to handle, with occasional guidance and supplementation by the specialist. Another 25% are referred directly to the care of a specialist either by virtue of the distance of the physician from the hospital or by reason of the complexity of the problem. In these cases, the specialist assumes the full role of management of the patient. The general practitioner, nevertheless, will usually see these patients several times a week and confer with the specialist about their management. On discharge the patient is returned to his referring physician with a detailed summary of his hospital stay together with specific recommendations regarding diagnosis and future management. The last 25% of patients consists of those cases in which the family physician, although retaining the attending role, will need and request formal consultation by the specialist because of a difficult diagnostic or therapeutic problem.

The director of the service makes rounds every day with his house staff and reviews in detail the studies made by the house staff and the attending physician. He sees every patient regardless of who the attending physician may be, and, if necessary, he can take additional history from the patient and examine him. He then confers routinely with the family physician concerned when the latter makes his own rounds. In this way the director of the service is able to supervise closely the general work of the service and can establish good standards of medical care with regard to diagnosis, management, and therapy. Each patient and his physician, in effect, have informal, routine consultations. When there are disagreements in management or diagnosis, these are discussed with the attending physician and not with the patient.

The general practitioner on his part is expected to see his patient, write admission and progress notes, communicate his orders to the house staff, and keep himself informed on the patient's progress. He carries the responsibility for admission and discharge and for communication with the family and patient regarding diagnosis, treatment, and so forth. He bills the patient for his services in the usual manner. There is no charge by the specialist for his over-all supervision but he does charge a fee in the usual manner for those patients directly under his care and for all formal consultations.

Every effort is made to preserve the role of the family doctor as the attending physician. The specialist staff firmly believes in the inviolability of this relationship. No major change in management is made by the house staff or the specialist without the prior knowledge and consent of the family physician.

On the surgical service the general practitioner is responsible for the preoperative and postoperative care of his patient and the management of concurrent medical problems. He may assist in major operative procedures. The teaching emphasis is on surgical diagnosis, the indications for operation, preoperative and postoperative complications, and minor surgical procedures.

Family physicians deliver 85% of the obstetric patients in this institution. The obstetrician-gynecologist is responsible for the establishment of standards of obstetric care. He has a knowledge of all deliveries performed, keeps careful check of the number and kind of services performed, and is available for all obstetric emergencies and complicated cases. All the gynecologic surgery is performed by the full-time specialist. The teaching technique is similar to that on the medical and pediatric services, and the emphasis is on prenatal and postpartum care, office practice of gynecology, and the physiology of normal labor.

The same type of continuous informal consultation about individual problems is available with the radiologist, the pathologist, and, indeed, all the other specialists in the hospital not only on inpatients but on the care of patients in the physician's own office The specialist is always available, and some of the most fruitful teaching occurs on the telephone, in the hallway, or over a cup of coffee

The specialists maintain offices in the diagnostic center and see patients there on referral by the family physician Twenty thousand such patients were seen last year These patients are returned to their family physicians with a diagnosis and recommendations for therapy Frequent telephone conversations, usually immediately after the examination of the patient in the diagnostic center, are followed by a formal consultation report Each of these contacts with the general practitioner is actively used as an opportunity for teaching by all members of the specialist staff

Opportunities for Continuance of Education

Informal Education—It is apparent that the opportunities for the continuance of medical education on the part of the practitioner when he is intimately integrated in the framework of such an institution are many and excellent Innumerable occasions are presented for reviewing current medical knowledge and information in the light of the problem at hand This is by far the most efficacious kind of teaching for the general practitioner The discussion of electrolyte problems in acidosis, for example, by means of a lecture usually has little permanent meaning for the busy practitioner A similar discussion, however, about a case of uremia with which he is concerned has greater pertinence and much more lasting value With this kind of relationship, the general practitioners are often stimulated to increase their own knowledge so that they can make a better contribution to the next discussion and improve their own management of the same situation in the future

Another important teaching feature is the indoctrination of the general physician with the concept of the hospital as a center for community health services Thus, he has ample opportunity to have contact with the whole breadth of ancillary medical services that are now available and necessary for optimum medical care, such as the departments of social service, public health nursing, psychology, rehabilitation, occupational therapy, and so on Also, he is daily introduced to some of the preventive health services not ordinarily found in a rural hospital For example, he is made familiar with the community educational activities carried on by members of the center staff, such as classes in weight control, parent education, and adult education and classes for diabetics Multiple screening is carried on in the evenings and reports are sent to the general practitioner All the community voluntary health agencies are housed in the center A child guidance service is available to which the general practitioner is able to refer his patients for diagnosis and management, and, as always, his opinion is solicited as an important part of the management plan A mental health unit is active under the direction of the psychiatrist, and the preventive aspects of psychiatry are emphasized as well as the importance of emotional factors in every disease process

Further, there are many exemplifications of the modern need for group thinking about the solution of complicated medical problems The practitioner becomes a member of many discussion groups concerning joint planning of patient care and is called upon to make contributions by virtue of his knowledge of the patient as an individual and his familiarity with the patient's environment

The general practitioner is exposed daily to the inquiring and stimulating minds of young house staff members and medical students He is encouraged to discuss his patients, and they are encouraged to ask him questions about diagnosis and management Often the general practitioner will join in making teaching rounds with the house staff and take part in the discussion of his own cases and those of other practitioners

On all services, particularly the services of medicine and pediatrics, the practitioners are constantly impressed with the basic science information necessary for the proper understanding of recent advances in clinical fields In every teaching activity, particularly those conducted at the bedside, the opportunity is grasped for emphasizing this type of information as being essential in the rational practice of medicine today Presentation of this material is made a natural part of every clinical conference

Formal Teaching—We shall speak only briefly of the more formal teaching activities since they are not peculiar to this institution and are considered less important in the continuing education of the practitioner A simple enumeration will suffice Each major clinical service has a weekly conference planned around patients and the problems of current interest Each Saturday clinical services rotate in presenting a correlative clinical conference, again using case material in the hospital, to the entire staff General practitioners are often placed on the program and asked to discuss the care of their patients Clinicopathological conferences are held monthly Didactic sessions in which there is emphasis on the pathophysiology and basic science substratum of disease entities are held once a week by the medical services

Many more instances of the formal and informal teaching activities of the Hunterdon Medical Center could be given For example, the participation of the general practitioner in the monthly medical audit of his own cases and those of the specialist staff and his presence on important hospital committees are excellent ways of acquainting him with the standards necessary for a good quality of medical care It is virtually impossible for a general practitioner serving as a member of the record committee, pharmacy committee, house staff committee, tissue committee, or others not to be influenced in the management of his own cases The necessity of objective, mutual, and constructive evaluation of the quality of medical care by one's colleagues is thus emphasized and made an essential part of practice

Comment

It would certainly be imprudent for those of us directly involved in this experiment to regard it as completed and of proved value in postgraduate education Our report is one of progress, and we can say that there is every indication that the method is certainly worthy of consideration as at least pointing to a solution of some of the problems of continuing education While a more objective evaluation of the merits of the Hunterdon experiment would be best made after many more years have elapsed, we think that there are a number of indications at present showing that its basic postulates are valid

There has been an increasing usage of the inpatient and outpatient facilities by the general practitioner to the point that the need for expansion is pressing Practically all the general practitioners and specialists associate on a first name basis, and social fraternization between both groups is a rule rather than an exception Personal relations have not been strained by this cooperative arrangement Most of the practitioners have accepted the idea of supervision and now voluntarily seek out the chief of the service on rounds to ask his opinion and recommendations regarding the care of the hospitalized patient It is worthwhile to note that, in the four years of the operation of what would appear to be a finely balanced scheme of professional relationships, there has not been a single situation in which a difference of opinion was not resolved by discussion between individuals The medical board has not been called upon to arbitrate a single dispute With very few exceptions, the patients have accepted examination by the house staff and supervision by the chief of the service They have not felt that their relationships with their own physicians were being disrupted thereby Community support in annual drives has been excellent

It is generally felt by the full-time specialist that the informal method of teaching has resulted in an improvement in the care of patients in the hospital and in the general practitioner's office Many of the general practitioners need progressively less direction and guidance in the care of the common medical, pediatric, and obstetric problems The full-time specialist staff has been well able to support itself on fees obtained through consultations and inpatient care

The process has not been a unidirectional one The specialists, too, have been educated by the association and have broadened their own experiences by contact with the general practitioners They have learned to respect and appreciate the difficulties in his position and the magnitude of the demands upon his time and energies They have had to continue their own educational progress by their weekly visits at New York University, by the preparation of their own teaching assignments, by the interchange of ideas with specialists in their own and other fields, by the conduct of research, and by the requirements of frequent consultations with practicing physicians in the solution of difficult clinical problems

We have learned that the general physician has a definitive role in rural medicine, is desirous to improve the care of his patients, and is eager to be taught as long as it is done in a patient, informal manner and without pretension We cannot predict the effect of this plan on the ultimate content of general practice in this community, but we feel that its presence will serve as an effective antidote to the 'Jack-of-all-trades' concept of general practice In our training of residents for general practice, we emphasize the idea of the family physician, based firmly in internal medicine, pediatrics, psychiatry, and possibly normal obstetrics It is men with this orientation who will probably provide the bulk of medical care in our area in the future, and the plan described should be equally effective in their continuing education

It would be misleading to imply that there have been no problems in this period of four years To make this concept work smoothly has required a cooperative spirit on the part of specialists, general practitioners, administration, board of trustees, and community—all of whom have been willing to yield some of their traditional sovereignties to achieve the objectives of optimum patient care It has been clearly demonstrated that the specialist staff would not be a threat to the economic status of the general practitioner The possibility of undermining the professional status of the general practitioner was foreseen early, and this has been diplomatically avoided by the specialist staff and by the practitioners themselves

A danger that has not materialized lies in the potentiality for such an arrangement to induce such a sense of security in the general practitioner that he will depend too heavily on house staff and specialist to carry out responsibilities that are properly his own

Summary

We have described four years of experience at the Hunterdon Medical Center, Flemington, N J, in an experiment in medical care and education that features the translation of the atmosphere and techniques of the university teaching hospital to a community rural medical center The essence of this attempt lies in the fullest exploitation of the teaching potentialities of a community hospital by the integration rather than the isolation of the practitioner, by the effective establishment of a local full-time teaching faculty, and by emphasis in continuing, informal, individualized postgraduate education

We think that this program offers some approach to a solution of the dilemma of continuing education It appears to be practicable and should be translatable to other communities, with certain modifications This method like all others can provide only an opportunity and a stimulus The ultimate hope lies in the orientation of the physician as a perpetual student, deeply ingrained with an attitude of sustained scholarship No community hospital program can substitute for this It can only offer an atmosphere in which the ideals of scholarship can flourish

CHALLENGES PRESENTED BY AND THE IMPORTANCE OF POSTGRADUATE MEDICAL EDUCATION

William A Sodeman, M D, Columbia, Mo

• *Many resources are now available to the physician who wishes to keep up to date The extent to which he utilizes them varies, he may neglect them entirely, or select what he thinks most suitable, or join a group in which attendance at certain meetings or courses is required There is evidence of a dearth of programs of postgraduate education specifically designed for general practitioners, and evidence that some of the programs given have left much to be desired The field bristles with challenges*

The very definition of postgraduate medical education adopted by the Council on Medical Education and Hospitals [1] establishes objectives The Council report includes in postgraduate education 'those educational activities engaged in by persons possessing the degree of Doctor of Medicine which are primarily designed to *keep them abreast of their own particular field in medicine* " These activities concern basic medical education as well as new developments in the field I shall discuss the importance of and challenges presented by this area

Of importance little need be said We are discussing the techniques and procedures that prevent decay in practice and that supply to the physician new advances in medicine at the consumer's level and the means of supplying the fresh advances for patient benefits To accomplish these ends the physician is, and should be, a lifelong student Indeed, medical education is a continuing process from undergraduate to graduate and finally through postgraduate phases The importance of education is obvious

Types of Programs

True, the problems change in each of these areas, and the program for the postgraduate must be as clearly defined as are those for the undergraduate and graduate [2] Here are the challenges! The field bristles with them Vollan's report [2] indicated that the physicians he surveyed gained their continuing education in five general ways—by reading the medical literature, by professional contacts, in hospital meetings, in medical society meetings, and through attending postgraduate courses The first three of these ways accounted for 90% of the time spent, the remaining two, 5% each

In undergraduate as well as graduate medical education, the student groups involved are fairly uniformly graded and the programs generally require full-time study In the postgraduate field these features, which lead to a relatively easily planned program, do not exist Each man's problems, needs, opportunities, time, stimulus, background of experience, and training vary widely Each man continues his education while in practice by the many means already mentioned

Reading the medical literature, contacting associates, consultants, and representatives of pharmaceutical companies, and attending hospital meetings are parts of routine activities in practice, are highly individual activities, and are conditioned by the motivation and attitude of the physician There is little that is compulsory, and each physician sets his own pace and seeks his own level Much help and guidance are needed here Experiments in the use of tapes, films, film strips, television, and correspondence courses to aid the physician in selecting and sorting out available literature show great promise Much remains to be done Even the additional methods of postgraduate training, attendance at medical society meetings, and especially attendance at more formal postgraduate courses are not compulsory, and again the physician sets his own pace The only group that has met the challenge of required training is the Academy of General Practice, which demands attendance at approved meetings and courses as a requisite for continued membership

Coordination of activities must be systematically planned In my own state of Missouri, for example, programs of county and district medical societies are planned in cooperation with the activities of the Academy of General Practice to provide effective scope and coverage Local hospital staff meetings and programs should be correlated and interrelated so that each physician can, by choosing state and national meetings to attend, along with selected refresher courses, tailor an over-all program to fit his needs Local guidance is important and is a vital need that remains unmet Stimulating the physician to participate actively in hospital and medical society meetings, by compulsion if necessary, is a tremendous challenge on the local front, where effective teaching talent is not always available Planned self-instruction of groups in local and regional institutions, with some outside help and guidance, has not generally progressed beyond the level of casual and infrequent reports at staff meetings When the physician-student actively participates and verbalizes, when he must visualize and organize, the learning process jumps in leaps and bounds In the following papers from the Conference on Postgraduate Medical Education, programs and experiments in this field and a number of facets of this tremendous problem will be considered These papers describe partial answers to the challenge of synthesis, organization, and integration of programs to round out and complete the needs of the practitioner

Need for Flexible Program

In the recent study of general practice in North Carolina by Peterson and his associates,[3] the number of formal postgraduate exercises attended did not correlate with the quality of practice observed Acquisition of journals did vary directly with the qualitative

---

Professor of Medicine and Chairman, Department of Medicine, University of Missouri School of Medicine

Read before the 53rd Annual Congress on Medical Education and Licensure, Chicago, Feb 11 1957 assessment of the physician's practice Some superior physicians took very little formal postgraduate education, and some of the poorest were very assiduous in this respect What is wrong here? The analysis beyond the record of the hours devoted to such activities is not clear Is it in the courses offered, in the reasons for attendance, in the men themselves, or in some other sphere? We all know too well some of the shortcomings of many of the formal courses given Ellis[4] has pointed out that the character of most instruction leaves much to be desired and that instruction is often carried out by techniques that were considered outmoded for medical students 50 years ago Undergraduate and graduate programs have "captive' subjects The student must learn mechanisms, items for which he might profess little interest and even direct antagonism, and aspects of health and disease that he dislikes, for he must qualify, pass examinations, or get official credit for licensure and certification, however, this is not so with the postgraduate He can skip what does not interest him, avoid the dull lecturer, walk out if unimpressed, and return only if, by his own evaluation and standards, he feels like doing so

Our most important challenge is to meet this heterogeneous, fluid, ever changing problem with a correlated, flexible, adaptable program that can be molded to fit the needs of the numerous groups concerned We must understand the persons with whom we are dealing and give the individual what he needs and wants Practicality does not permit us to go back to the choice of students entering medicine, to choose those who will be eager for continued study and who would strive to get it That area is being diligently explored Even if we go back and make the attempt, we really do not know how to choose students in this respect We must take the groups available and sell them the right product We have no monopoly of the physician's time as we have in the other fields of medical education We must interest him, compete with indifference, and sell him a product he will buy and with which he will be so satisfied that he will return for more Selling soap or automobiles could be much easier!

In respect to postgraduate education, there are three groups of physicians those in one group go to any means for continued education, those in another shun any opportunities even when given them, and those in a third large group will take advantage of the opportunities if easily available or if put within reasonable reach It is a great challenge to reach those needing the program The Vollan report[2] stated that less than 5% of the hours of programs offered were specifically designed for general practitioners, who make up about half of the potential consumers of postgraduate education Does this show that the challenge is being met?

Status of Postgraduate Programs

The blueprinting of the over-all needs for the area and the working out of an integrated program would make it possible for physicians to organize their own schedules to include refresher education as a part of their regular programs[2] To improve on didactic methods, choice of other techniques of presentation, such sessions as group discussion, workshop exercises, casework, and panels, especially in the physician's own institutions and geographical area, require skillful planning for effectiveness Personnel, time, and finances of educational units are not adequate for continued education of the physician Inspection and approval of formal courses to insure adequacy do not exist The challenge is far from met The postgraduate program is a stepchild to the other programs that have attained, despite the sharp controversies concerning approach and content, a tremendously high plane Postgraduate programs—the training programs designed to keep the physician's knowledge adequate over the 30 to 40 years of his practice—still do not have their rightful place beside the other programs What a challenge this is!

I have already spoken of the skills and salesmanship necessary in the teaching of this critical and sensitive group ~~Physicians leave their~~ practices, ~~give up in~~come, and deny services to their patients to attend the sessions set up for them The sessions must be worthy of this sacrifice Yet, in a large part, formal postgraduate education has not achieved a place in teaching institutions equal to the needs Too often the programs are incorporated into the operation established for undergraduate or graduate programs and are looked upon by the institutions as an added burden These inadequacies are reflected in the teachers Indeed, interest shown by the teacher is often lukewarm, which reflects in student response This is understandable if teaching these courses is forced upon the instructor as an added job—an activity he does not want and that he does not consider an integral part of his work—and as a duty taking time he really wants for research and writing He often does not understand his audience or indeed the problems his pupils face Frequently he has never faced them himself He may expound on techniques of pH determination or on the management of acid-base balance not available to 5% of those to whom he is talking and not understood by many more He may describe details of operative procedures and leave the group entirely baffled Sometimes he bypasses the real problem confronting him because of lack of success with the techniques used I recall one such professor who abandoned the course in his field for general practitioners These were the reasons, which, of course, he did not realize Still, he was successful in use of the techniques of graduate medicine in refresher courses for specialists in his field, but he was not reaching the groups really needing the instruction

Many teachers are willing to take exercises, such as formal lectures to large groups, prestige appearances, presentations at society meetings when they are 'the program," or dissertations to groups from which potential referrals may come Such exercises have their place, but, if this is the postgraduate program, it is but paying lip service to the problem

Please do not believe from the above remarks that I consider all to be chaos in this field There are institutions dedicated to the problem where postgraduate education has taken its rightful place and there are teachers with enthusiasm and understanding both in these institutions and in those dedicated basically to undergraduate and graduate instruction, but these men are too few We have the great challenge of finding, training and developing teachers skilled in meeting postgraduate groups, poised in handling the difficult individuals and awkward situations in discussions, experienced in the problems outside medical centers, adept in choosing proper material for demonstrations, lectures, seminars, and panels, and interested and concerned about postgraduate education as an important and integral part of their daily responsibilities

Finance is a great challenge Undergraduate programs suffer from inadequate funds The undergraduate pays one-third or less of the institutional cost of his education, someone else must pay the remainder Postgraduate education is still more complex Travel is more costly Groups are small and their programs intermittent The doctor loses income at home when he is away Can and should the postgraduate course pay its own way? If the answer is either yes or no, how is the challenge of finance to be met?

Summary

The importance of postgraduate programs is undoubted The field bristles with challenges I have pointed up some of those that I consider of major importance There are many others Some of these problems rest upon the many facets of the program and the greatly varied needs and interests of the postgraduate student In undergraduate and graduate programs, the scope is fairly well defined This is not true in postgraduate education It is a heterogeneous field Regional needs vary and planning and correlation are very important How do we reach those with the greatest need? How do we improve self-education on the home front? What of compulsory programs? How do we coordinate and synthesize a complete program when there are such varied needs, agencies, or areas of teaching? Some courses must be long, some short, some on simple techniques or problems, some on general fields, some in specific areas, some concentrated, some intermittent, and some inside and some outside the institution Where do we get worthy interested teachers? How do we solve the problems of responsibilities and finances? What of standards, inspection, and approval of formal courses? All these problems combine with the need for sandwiching programs into and making them part of the activities of practice Much of this is responsible for the lag in the elevation of postgraduate education to its proper place alongside the other fields of medical education To solve these problems is the great challenge Postgraduate education must become of age" We must face up to the problems

CURRENT ACTIVITIES IN POSTGRADUATE EDUCATION OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Glen R Shepherd, M D, Chicago

• *An ad hoc advisory committee was appointed a year ago for study of useful approaches for improving the quality of postgraduate courses and other educational programs for physicians The initial recommendations of the Committee to the Council on Medical Education and Hospitals is publication of a statement of objectives and basic principles These include emphasis on use of clinical facilities, more effective educational methods, and the need for appraisal of courses, each of which is briefly discussed in this paper*

In order to best explore the problems in the field of postgraduate medical education and useful approaches to their solution, the Council on Medical Education and Hospitals decided that it should have the advice of leaders in the profession having a diversity of backgrounds in and viewpoints on practice and medical education An *ad hoc* advisory committee on medical education was appointed a year ago

Postgraduate programs of hospitals and medical schools, sometimes in cooperation with medical societies, involve groups of people and methods that have close analogies with undergraduate and graduate medical education In fact, all three phases may, and often do, involve the same educators As a consequence, in planning and talking about the continuing education of physicians, we are dealing with a part of medical education as a whole rather than with some unique and intangible kind of thing It is true, as Dr William A Sodeman said (page 366), that the practicing physican-students are more mature and present other differences because of their practices and family responsibilities Even so, it would seem that the vitally effective elements of undergraduate and graduate medical education might well apply to the postgraduate aspect

Need of Reappraisal

This kind of thinking has not characterized some of the programs labeled as educational for physicians Because of lack of considered objectives, lack of coordination with the parent body of medical education,

---

Assistant Secretary, Council on Medical Education and Hospitals of the American Medical Association

Read before the 53rd Annual Congress on Medical Education and Licensure Chicago Feb 11 1957 and, generally, lack of applying the lessons already so painfully learned in the other phases of medical education, the postgraduate part has grown like Topsy, with the inevitable and confusing results of jerry-building As Dr Osler Peterson and colleagues[1] concluded in their recently published analytical study of general practice in North Carolina The nebulous influence of postgraduate study on the physician's performance suggests that a reappraisal of the methods employed in postgraduate courses is overdue [2]

Peterson and colleagues are too kind in using the word 'reappraisal' Too often there was never an initial 'appraisal' of the methods Considering that their study was limited to a relatively small number of physicians in a single state and that it lumped together all kinds of medical meetings with postgraduate courses, we can use his conclusion as being more a straw in the wind than a definitive indictment However, scrutiny of the methods employed was a part of the Vollan survey[3] as well as of the deliberations of the Advisory Committee on Postgraduate Medical Education of the Council on Medical Education and Hospitals In particular, the Committee felt the reservation so well expressed by Dr Samuel Johnson when he said, People have got a strange opinion that everything should be taught by lectures [4] One might say, though, as Dr David Sinclair, the British educator, observed, 'The visiting expert is in the American tradition and so is the capacity to sit and be edified by a variety of long-winded discourses' [5]

Location of Postgraduate Education Programs

During the initial deliberations of the Advisory Committee, it was acknowledged that this field involves as sponsors medical schools, hospitals, and medical societies It also became clear that adequate medical education requires clinical facilities with patients, laboratories, libraries, conference rooms, and audiovisual materials—in short, the usual facilities of a medical school or a teaching hospital Therefore, it seemed reasonable for the Committee to recommend that hospitals and medical schools should be the location of postgraduate educational programs This would mean that medical societies could function best in this field by working cooperatively with hospitals and medical schools in the area, with these institutions serving as the locations of any primarily educational programs—that is, in fact, the way the American College of Physicians functions in its courses each year throughout the United States

In this regard, the present interest of medical schools is of importance Last summer, as part of the annual query by the Council of medical schools in the United States for information needed to prepare the Annual Report on Medical Education, a special questionnaire on the postgraduate phase was sent to the dean of each school In response to a question about the sense of responsibility that the school felt regarding the continuing education of physicians, 72 medical school faculties expressed in various ways some sense of responsibility Of these, 40 schools' questionnaires contained a statement that indicated that postgraduate medical education was one of the major educational activities of the school, along with the fulfilling of the responsibilities for undergraduate and graduate medical education [6] Dr James W Colbert Jr, chairman of the committee on continuation education of the Association of American Medical Colleges, in his report for the committee to the 67th annual meeting of the association last November, said in part, 'The continued education of the physician is best assured by the establishment of an intellectual and educational environment supporting the responsibility of patient care Such an environment will certainly require academic leadership and thus the role of the medical school will probably become greater rather than less' [7]

Statement of Objectives and Principles

It also became apparent to the Advisory Committee that a statement of the objectives and basic principles of postgraduate programs needed to be prepared as a first step in evolving a plan of action It seemed impossible to make sensible recommendations to the Council of ways it could be of maximum assistance in this field unless the purposes or objectives of this field were more clearly defined Assuming the correctness of the hypothesis that this field is a part of medical education and can benefit by applying what has been learned in developing undergraduate and graduate programs, the Committee thought that this experience could be distilled into a number of general principles as a guide for those responsible for postgraduate medical education Such a document has been developed

The first recommendation that the Advisory Committee made to the Council was that a brochure containing the objectives and basic principles of programs of postgraduate medical education be prepared and submitted to the Council for publication and general distribution Its purpose would be to provide a basically sound approach, based on the common denominators of medical education, that could be applied to the various formats and types of postgraduate programs for their improvement The Council on Medical Education and Hospitals approved the document for submission to the House of Delegates of the American Medical Association in June, 1957 The interested groups that Dr Victor Johnson mentioned—including the Association of American Medical Colleges, the American Hospital Association, the American Academy of General Practice, the American College of Surgeons, the American College of Physicians, the Advisory Board of Medical Specialties—are being consulted in this first step, as they will be in later steps, in the Council's course of action, because only by going forward cooperatively and with generally agreed upon approaches can the challenges in this field be met

If you will bear in mind that the guide has not yet been approved by the House of Delegates and so cannot be taken as an official statement of the American Medical Association, I would like to go over with you the present draft of the statement of objectives and basic principles Please assume that, after each principle, from a paragraph to more than a page of explanatory material appears, which indicates in a general way how the principle could be applied by hospitals, medical schools, and medical societies in their programs.

Parenthetically, please note that the word "program" has been used throughout the guide to denote not only a formal postgraduate course or series of courses but the educational activities sponsored by community hospitals, often in cooperation with medical schools. A basic document such as this should be flexible enough to apply to any primarily educational program planned by groups of physicians, including supplementary and experimental programs with use of television and audiovisual aids. The programs to which this statement is not intended to apply are medical society business and social meetings and conventions, because they cannot be considered primarily educational programs.

The guide in its present draft gives the following objectives of postgraduate medical education:

> The ultimate aim of postgraduate medical education is to make it possible for each physician to use in his practice the modern medical knowledge that continuously becomes available. Adequate professional growth ensues through the participation of each physician in suitable programs of continuing education in addition to his own experience and reading.
>
> Postgraduate educational programs should as a result of current advances in the basic science and clinical fields favorably augment and modify an adequate initial education. These programs should make possible the acquisition of such new skills in the field of original competence as scientific advances require. Furthermore, they should strengthen the habits of critical inquiry and balanced judgment that denote the truly professional and scientific man.

If the following basic principles seem simple, do not be surprised. Truly basic principles usually are simple. There is no attempt to mystify—rather the idea is to guide by pointing out the broad essentials. The essentials as given in the guide are as follows:

> 1. There should be administration of the postgraduate program by a responsible person having the respect and support of the professional staff of the organization or institution, an administration having as its goal an educational program in the highest interest of the medical profession, as epitomized in the objectives previously stated. There should be continuity of administration, evidence of careful advance planning of the program, and a suitable voice by the teaching staff in the postgraduate program.
> 2. The budget should be adequate to the educational program undertaken and to its continuing improvement.
> 3. The teaching staff should consist of physicians and their associates of proven ability, training, and experience with an interest in and dedication to the development of carefully planned educational programs in the best current intellectual and professional interest of the participating physicians.

I would like to quote a few points from the explanatory material pertaining to this principle:

> There should be an adequate number of instructors for each program to permit the use of the more effective participative methods of education. In the other phases of medical education and in other fields of education, the number of students per teacher becomes much smaller as education becomes more advanced. This would seem to have significant implications in postgraduate medical education.
>
> Instructors participating in any course or other educational program should be capable of providing explanation of the basic science mechanisms of health and disease and their clinical applications in the prevention, diagnosis, and treatment of disease. The essence of professional knowledge, as compared to purely vocational, is understanding of the basic science to provide a "know-why" as well as a "know-how" of the practice of medicine.
>
> The resident staff of a hospital and particularly of a community hospital may form a valuable part of the teaching personnel of a postgraduate program.

To return to the principles:

> 4. The curriculum of any postgraduate medical education program should be the result of thoughtful planning well in advance of the date scheduled for the beginning of the program.

With reference to the words "thoughtful planning," the explanatory material adds in part,

> Thoughtful planning also means that the content of courses and of other programs should be based upon the demonstrated needs and wishes of the physicians of the region, as well as upon advances in medicine. The means of ascertaining the needs and wishes of physicians will vary. Of great assistance is a close and cordial liaison among medical societies, medical schools, and hospitals of the region.

The explanatory material on curriculum also states:

> Attention to the newer knowledge of the basic mechanisms of disease and of treatment should be a part of postgraduate programs along with the more immediately applicable information.

> 5. There should be available facilities that encourage participative methods of education. Though lectures by professionally well qualified speakers are a means whereby physicians obtain information, it is felt that such a method of education cannot alone provide an adequate postgraduate program in the context of modern education. The facilities mentioned above should include the availability when appropriate to the content of the program of patients and their case records and other necessary records such as roentgenograms, electrocardiograms, surgical pathology tissues and/or reports, laboratories, library, conference rooms, classrooms, and audiovisual aids—all adequate for and suitable to the specific program.

This principle simply elaborates the conclusion of the Committee that I mentioned earlier, that hospitals and medical schools are the proper places for medical education, including the education of the physician in practice. The word "alone" with reference to lectures indicates that they have a place but cannot carry the whole burden of education. The explanatory material states:

> A hotel ballroom or a lecture hall used alone and isolated from a hospital or medical center does not provide those essential facilities needed in modern medical education whether it be for students working toward the M.D. degree or for physicians in practice enrolled in a course or participating in other primarily educational programs.

The principles continue as follows:

> 6. The educational methods should include more than a series of lectures or panel discussions in which the physicians are primarily passive recipients. Methods requiring active participation include live clinics and ward rounds, seminars, open question periods, laboratory work, and study of patients under supervision.

Regarding principle 6, I will say only that it is followed by the longest explanation because the Advisory Committee felt this to be a major problem area.

> 7. Methods of evaluating the effectiveness of postgraduate programs should be developed.

A very brief paragraph of explanatory material encouraging experimentation in ways of better accomplishing such evaluation and suggesting the educational and evaluative implications of medical audits follows principle 7

> 8 Each physician's reward for participation in postgraduate medical education always should be his improved ability to care for his patients and the stimulation of his own spirit of intellectual adventure

There is a short paragraph of explanation under this final principle that I would like to quote

> Any certificate granted at the completion of a postgraduate program or series of programs should not be or resemble a diploma attesting to special skill or be reasonably susceptible of such interpretation Postgraduate medical education is not intended to provide an educational experience adequate for beginning the practice of a specialty or subspecialty That is the concern of graduate medical education, that is, residency and fellowship training Therefore, it would be inappropriate for any document attesting to postgraduate study to be subject to misinterpretation

These are the principles, but by no means has the complete text of the document been given This general guide is the first step in the course of action recommended by the Advisory Committee to the Council and endorsed by the Council It is quite possible that more specific guides may be developed based on experience with the basic guide and on the wishes of the profession

Appraisal of Postgraduate Courses

The second recommendation by the Advisory Committee was that the Council give consideration to appraisal of postgraduate courses and apply the results of such appraisal to the preparation of the annual list of courses published in THE JOURNAL of the American Medical Association This would be consistent with the Council's policies in listing medical schools, internships, and residencies—policies that have been productive of real educational advances

Such an appraisal would also seem desirable in itself to indicate those courses that are educationally worthy of the physician's time and money It has been shown that courses of high quality stimulate physicians to seek such education while a poor course is most discouraging to a physician's further participation and furnishes justifiable cause for his disappointment at the organization, quality, content, or methodology

A further reason for advocating a continuing appraisal of postgraduate courses would be that such a plan would almost surely attract thoughtful attention to the basic guide as well as provide an additional incentive for the sponsors of programs to improve their offerings The present annual list of unappraised courses and miscellany actually may be injuring the chances of raising educational standards in this field by giving tacit approval to some unworthy activities Methods of appraising courses and other postgraduate medical educational programs are under active study by the Advisory Committee and by the Council itself, and the advice of the interested groups already mentioned will be sought

Means of Increasing Participation in Postgraduate Education

A third step recommended to the Council by the Advisory Committee poses perhaps the most thorny problem of all It is the recommendation that suitable means be developed for increasing the number of physicians who regularly participate in programs for their continuing education

I suppose that, in an ideal culture, no outside stimulus, incentive, or recognition would be required because each physician would eagerly seek out, at any personal sacrifice, every available means of continuing his education solely because of an inner urge and an intellectual dissatisfaction with the *status quo* of his knowledge and skill I do not expect this millenium to occur overnight I do hope that a wider recognition of the important relationship of postgraduate medical education to the quality of medical care, coupled with an increased educational stature of the available programs, will attract many more physicians However, the emphasis should be on quality To date there has been too much attention given to quantity alone—to the number of physicians attending and the number of courses—and far too little attention given by many persons to the educational quality of the programs While the availability of a sufficient quantity of meritorious educational opportunities is the ultimate goal, it would seem that attention to the quality of each program would best insure our reaching that goal

It is probable that inculcating habits of scientific thought in medical students today will cause them to use their educational opportunities tomorrow and throughout their careers so that their knowledge will continue to be current As Sir Henry Cohen, professor of medicine at the University of Liverpool, said at the first World Conference on Medical Education, Above all, since medical knowledge is ever expanding, the undergraduate medical curriculum must favour the acquisition of enduring habits of work and thought and enthusiasm for study, so that the doctor shall remain a student throughout his professional life'[8] It seems to me that the future of postgraduate medical education lies with and should be planned to interest those physicians now recently out of their graduate medical education so that their competence in practice will continue at a high level as judged by the then current knowledge and skills

This matter of finding means of stimulating participation by more physicians in postgraduate educational programs year after year will come under more active study by the Advisory Committee of the Council in consultation with other interested groups However, *the necessary preceding step would seem to be the* giving of attention to the quality of the postgraduate medical education available A general improvement in quality could, in itself, provide sufficient incentive, especially to the physicians who have graduated more recently

Collection and Dissemination of Information

A fourth step recommended by the Advisory Committee is that the Council on Medical Education and Hospitals act as a central point nationally for the col-

lection and dissemination of information in this field The Council has been increasingly active in this capacity in the past few years

This symposium, Postgraduate Medical Education, is directly related to this function of the Council of acting as a "clearing house" In the past, attention has been largely on formal courses and comparatively little on other approaches to the continuing education of physicians The papers of this symposium will concentrate on hospital activities in non-course education for practicing physicians

One is often hard put to clearly delineate where, in such programs, the graduate medical education of interns and residents merges with the postgraduate medical education of the visiting staff Every time I try to teach, I learn more than I teach, and this is also the usual experience of others Certainly, when the visiting staff of a hospital is thoroughly involved in a well-planned and effective graduate educational program, the practicing physicians learn along with the residents It is a participative and highly motivated situation for each, not a passively didactic one It is truly continuous—not episodic While I do not suggest that such hospital programs can replace formal postgraduate courses, it seems apparent that the hospital non-course programs have a much larger educational potential than has been realized except in a few places In order to examine some of the possibilities and especially to pique interest in thinking of locally applicable variations, papers on four different examples of such programs were included in the symposium and appear in this issue of THE JOURNAL Dr Delp and co-workers on the University of Kansas program (this page), Dr Wilkinson on the New York University plan (page 381), and Dr Towsley on the University of Michigan plan (page 377), and Dr Pellegrino describing the educational significance of the Hunterdon Medical Center

UNIVERSITY OF KANSAS PROGRAM IN POSTGRADUATE MEDICAL EDUCATION

Mahlon Delp, M D, Jesse D Rising, M D
and
William D Nelligan, B S, Kansas City, Kan

• *Experience with postgraduate instruction in medicine has been continuous in Kansas since 1911, when the University of Kansas School of Medicine and the Kansas State Board of Health cooperated to arrange the first annual five day summer school for health officers and physicians The idea has evolved into the present program of postgraduate medical education, in which the university supplies administration, curriculum, faculty, facilities, budget, educational methods, and evaluative procedure with the advice and cooperation of several other organizations, especially a committee for postgraduate study appointed by the Kansas Medical Society The program has been amplified to include work for specialists as well as generalists and for several professions allied to medicine The use of participative methods of education, rather than lectures alone, is characteristic and vitally important The enlisting of basic science instructors along with clinical instructors in the teaching teams is beneficial to both groups The program is assured of acceptance if a mutually profitable relationship with the student body exists, and this can be insured only by continuing critical self appraisal*

With the exception of the years 1922 and 1926, the University of Kansas has offered some type of postgraduate instruction in medicine almost continuously for the past 45 years Such instruction began in June, 1911, with a cooperative venture between the University of Kansas School of Medicine and the Kansas State Board of Health in arranging and presenting, on the Lawrence campus, the first annual five-day summer school for health officers and physicians After the first three years, these courses were transferred to the school of medicine at Kansas City and were expanded to two full weeks annually

In 1927, the university extension division and the school of medicine offered their first courses on the circuit plan, using six centers in the state of Kansas for the original trial In 1928, five short courses were added to the activities and became permanent fea-

---

Professor of Medicine and Chairman of Department of Postgraduate Medical Education (Dr Delp), Associate Professor of Medicine and Pharmacology (Dr Rising), and Executive Director of Postgraduate Medical Education (Mr Nelligan), University of Kansas School of Medicine

Read before the 53rd Annual Congress on Medical Education and Licensure, Chicago, *Feb 11, 1957* tures In 1942, the president of the Kansas Medical Society requested the cooperation of the University of Kansas and the Kansas State Board of Health in providing intensive circuit-type courses for physicians of the state Representatives of the three organizations were assembled as a joint advisory committee for the first planning session early in 1943 This union of energies has been continued to the present time

The creation of the department of postgraduate medical education of the school of medicine, in 1945, served to stimulate expansion of all postgraduate activities This step represented the attainment of a degree of maturity in the administrative structure, permitting organized planning, unified administration, and development of policy based upon sound principles in medical education Although chief responsibility for the entire program rests immediately upon the university and the medical school, the state medical society still retains co-sponsorship through its committee for postgraduate medical study The whole program of postgraduate medical education in Kansas is an integral part of the Kansas plan for rural medical care, formulated in 1948

This is the historical background of one program of postgraduate medical education, which may be considered a prototype of programs involving a medical school and a state medical society The barest fundamentals in any educational project however, are a student, a teacher, and a curriculum, therefore, postgraduate medical education may be, and is, carried on in a successful manner using other methods

Organization

The topmost administrative body of the University of Kansas is its board of regents, to whom the chancellor is directly responsible He and the deans of the various schools formulate policy in an administrative pattern common to most state universities The dean of the medical school, with the aid of his faculty guides activities and controls policy within the school Postgraduate medical education is designated as a distinct function of a separate department within the medical school As such, it has its own responsibilities, prerogatives, and the usual amount of autonomy Department administration is carried on by a chairman and an executive director

The Kansas Medical Society has an administrative structure similar to other such state organizations It has a committee for postgraduate study Working directly with the medical school is a joint advisory committee composed of the representatives of the committee for postgraduate study of the medical society, the chairman of the committee on medical schools, the chairman and one member of the committee on rural health, one official from the Kansas State Board of Health, one official from the Kansas Academy of General Practice, and additional selected persons These interested persons join with the chairman of the department of postgraduate medical education and the dean of the school of medicine as an actual working and policy-making group The term "working" is used advisedly, because this group annually spends from 8 to 10 hours in session, discussing the past year's activities and problems facing the department and actually building in outline the content and format of programs for the ensuing year

It might seem that the organizational structure is too bulky and loosely bound for good administration, but experience has proved this to be not so The program administration, in the last analysis, falls directly and properly upon the medical school The medical school also supplies the other essentials curriculum, faculty, facilities, budget, educational methods, and evaluation to the enterprise

Objectives and Purposes

The objectives of this program, as outlined in our last annual report, are—as might be expected—similar in general terms to all other such programs Medicine has become so complex that it is obviously not possible to provide a completely detailed and sustaining knowledge concerning every medical and related discipline during a four-year period of study Consequently, four years of undergraduate medical study, internship, and even residency supply merely the foundation for a lifelong study of medicine Continuation of study aimed at the physician's acquiring new knowledge and skills, renewing former ones, and preserving and increasing professional competence constitutes postgraduate medical education Providing the environment and atmosphere for accomplishing this is the objective of the Kansas program

Formerly designed for and directed at the generalists in our region, the program is now geared to the needs of every physician, regardless of his interest or field of specialization Preservation of competence, renewal of former skills, and acquisition of new knowledge is a need of all physicians, not of one group alone The prime responsibility of the Kansas program is to the physician of Kansas, but, feeling a regional responsibility and encouraged by a regional response, the department no longer regards the state boundaries as valid limitations to its activities

No longer are all programs prepared exclusively for physicians We now recognize the need for providing continuation education for ancillary medical personnel, such as nurses, technicians, physical therapists, and others More recently, we have assumed the responsibility for a fourth phase of medical education namely, that of health education for the lay public The real aim of all medical education should be improving the health of our people Increasing the skills of all those engaged in medical care and increasing the understanding regarding health matters for those receiving the medical care are, therefore, prime objectives This final statement also indicates quite clearly our potential student body

Scope and Structure of Present Program

An immediate view of this program can be gained by examination of the course offerings and the enrollment A characteristic of all the courses (see table) is the use of participative methods of education in courses other than rounds, clinicopathological conferences, laboratory work, seminars, or live clinics rather than use of lectures alone

lection and dissemination of information in this field The Council has been increasingly active in this capacity in the past few years

This symposium, Postgraduate Medical Education, is directly related to this function of the Council of acting as a 'clearing house' In the past, attention has been largely on formal courses and comparatively little on other approaches to the continuing education of physicians The papers of this symposium will concentrate on hospital activities in non-course education for practicing physicians

One is often hard put to clearly delineate where, in such programs, the graduate medical education of interns and residents merges with the postgraduate medical education of the visiting staff Every time I try to teach, I learn more than I teach, and this is also the usual experience of others Certainly, when the visiting staff of a hospital is thoroughly involved in a well-planned and effective graduate educational program, the practicing physicians learn along with the residents It is a participative and highly motivated situation for each, not a passively didactic one It is truly continuous—not episodic While I do not suggest that such hospital programs can replace formal postgraduate courses, it seems apparent that the hospital non-course programs have a much larger educational potential than has been realized except in a few places In order to examine some of the possibilities and especially to pique interest in thinking of locally applicable variations, papers on four different examples of such programs were included in the symposium and appear in this issue of THE JOURNAL Dr Delp and co-workers on the University of Kansas program (this page), Dr Wilkinson on the New York University plan (page 381), and Dr Towsley on the University of Michigan plan (page 377), and Dr Pellegrino describing the educational significance of the Hunterdon Medical Center

Professor of Medicine and Chairman of Department of Postgraduate Medical Education (Dr Delp), Associate Professor of Medicine and Pharmacology (Dr Rising), and Executive Director of Postgraduate Medical Education (Mr Nelligan), University of Kansas School of Medicine

Read before the 53rd Annual Congress on Medical Education and Licensure Chicago Feb 11, 1957 tures In 1942 the president of the Kansas Medical Society requested the cooperation of the University of Kansas and the Kansas State Board of Health in providing intensive circuit-type courses for physicians of the state Representatives of the three organizations were assembled as a joint advisory committee for the first planning session early in 1943 This union of energies has been continued to the present time

The creation of the department of postgraduate medical education of the school of medicine, in 1945, served to stimulate expansion of all postgraduate activities This step represented the attainment of a degree of maturity in the administrative structure, permitting organized planning, unified administration, and development of policy based upon sound principles in medical education Although chief responsibility for the entire program rests immediately upon the university and the medical school, the state medical society still retains co-sponsorship through its committee for postgraduate medical study The whole program of postgraduate medical education in Kansas is an integral part of the Kansas plan for rural medical care, formulated in 1948

This is the historical background of one program of postgraduate medical education, which may be considered a prototype of programs involving a medical school and a state medical society The barest fundamentals in any educational project however, are a student, a teacher, and a curriculum therefore, postgraduate medical education may be, and is, carried on in a successful manner using other methods

Organization

The topmost administrative body of the University of Kansas is its board of regents, to whom the chancellor is directly responsible He and the deans of the various schools formulate policy in an administrative pattern common to most state universities The dean of the medical school, with the aid of his faculty, guides activities and controls policy within the school Postgraduate medical education is designated as a distinct function of a separate department within the medical school As such, it has its own responsibilities prerogatives, and the usual amount of autonomy Department administration is carried on by a chairman and an executive director

The Kansas Medical Society has an administrative structure similar to other such state organizations It has a committee for postgraduate study Working directly with the medical school is a joint advisory committee composed of the representatives of the committee for postgraduate study of the medical society, the chairman of the committee on medical schools, the chairman and one member of the committee on rural health, one official from the Kansas State Board of Health, one official from the Kansas Academy of General Practice, and additional selected persons These interested persons join with the chairman of the department of postgraduate medical education and the dean of the school of medicine as an actual working and policy-making group The term "working" is used advisedly, because this group annually spends from 8 to 10 hours in session, discussing the past year's activities and problems facing the department and actually building in outline the content and format of programs for the ensuing year

It might seem that the organizational structure is too bulky and loosely bound for good administration, but experience has proved this to be not so The program administration, in the last analysis, falls directly and properly upon the medical school The medical school also supplies the other essentials curriculum, faculty, facilities, budget, educational methods, and evaluation to the enterprise

Objectives and Purposes

The objectives of this program, as outlined in our last annual report, are—as might be expected—similar in general terms to all other such programs Medicine has become so complex that it is obviously not possible to provide a completely detailed and sustaining knowledge concerning every medical and related discipline during a four-year period of study Consequently, four years of undergraduate medical study, internship, and even residency supply merely the foundation for a lifelong study of medicine Continuation of study aimed at the physician's acquiring new knowledge and skills, renewing former ones, and preserving and increasing professional competence constitutes postgraduate medical education Providing the environment and atmosphere for accomplishing this is the objective of the Kansas program

Formerly designed for and directed at the generalists in our region, the program is now geared to the needs of every physician, regardless of his interest or field of specialization Preservation of competence, renewal of former skills and acquisition of new knowledge is a need of all physicians, not of one group alone The prime responsibility of the Kansas program is to the physician of Kansas, but, feeling a regional responsibility and encouraged by a regional response, the department no longer regards the state boundaries as valid limitations to its activities

No longer are all programs prepared exclusively for physicians We now recognize the need for providing continuation education for ancillary medical personnel such as nurses technicians, physical therapists, and others More recently, we have assumed the responsibility for a fourth phase of medical education namely, that of health education for the lay public The real aim of all medical education should be improving the health of our people Increasing the skills of all those engaged in medical care and increasing the understanding regarding health matters for those receiving the medical care are, therefore, prime objectives This final statement also indicates quite clearly our potential student body

Scope and Structure of Present Program

An immediate view of this program can be gained by examination of the course offerings and the enrollment A characteristic of all the courses (see table) is the use of participative methods of education in courses other than rounds, clinicopathological conferences, laboratory work, seminars, or live clinics rather than use of lectures alone

A total of 3,760 persons were enrolled in the postgraduate program from July 1, 1955, through June 30 1956, with 2,319 physicians included in the total The number of physicians enrolled in symposiums was 1,417, in intermittent courses, 546, in correspondence courses, 299, in courses in advanced, clinical, and investigative techniques, 53, and in clinical traineeships, 4 Total enrollment of persons engaged in allied and ancillary fields was 1,441 during the same period There were 6 doctors of philosophy enrolled, 52 doctors of dental science, 199 medical technicians, 692 registered nurses, and 492 lay persons

Local Attitudes Toward Postgraduate Education

During the past 10 years, the Kansas program of postgraduate education has matured, becoming an effective and quite extensive enterprise in continuation education This situation, however, came about after almost 40 years of effort The step in the program's development that has been the most recent and that has given it the greatest stability was the creation of the department of postgraduate medical education within the medical school This provided the needed administrative structure Of equal importance and coming earlier in the development of this program was the cooperation with the potential student body represented in the state medical society These two features would not have been sufficient to establish the program without the wholehearted acceptance by the dean of the medical school and the university administration of postgraduate education as a part of the responsibility of a medical school This acceptance was outlined very clearly by the administration in 1948 as a part of the Kansas plan for rural medical care

Courses in Postgraduate Medicine Offered by the University of Kansas School of Medicine, 1956 1957

For the Medical Profession

Symposiums (short courses)
Obstetrics
Internal medicine
Pulmonary disease clinic
Gastroenterology
Surgery
Radiology and radioactive isotope
The heart cardiac arrhythmias
Neurology
Symposium on pain
Pediatrics
Electrocardiography
Hematology
Ophthalmology and otolaryngology
Anesthesiology
Cardiac auscultation
Symposium on leptospirosis

Intermittent courses
General practice
Surgery—operative clinics

The public voicing of this responsibility of the medical school, which was expressed in such a manner as to impress every faculty member, met with the spontaneous approval of the Kansas Medical Society It was an important step in renewing a desirable relationship with the practicing physicians within the state

There has evolved in Kansas a working relationship between the state medical society and the medical school of the state university that has made possible an increasingly mature and extensive program of medical education At no time in this relationship between the society and the medical school has there been conflict or friction that in any way impaired the prerogatives or fundamental policy of the school The Kansas Medical Society with the postgraduate study committee has functioned as a helpful advisory committee and has at no time attempted to dictate policy Such a pleasant relationship is in part the result of the medical school's approval of the over-all program and of the real acceptance by the society of this program as 'their program,' primarily designed for them with their help and for which they have a paternal attitude

The faculty of the school of medicine has, by years of close association with the postgraduate program, become more sympathetic toward the additional burden of this phase of teaching When the faculty was smaller, resistance did exist, but it was lessened by the wholehearted acceptance by the dean and the university administration of postgraduate education as a part of the school's responsibility The structuring of a new department of postgraduate medical education with a departmental chairman, an executive director, and adequate personnel to do much of the routine work added a new dignity to the local program and administrative sanction to its permanence All of this served to diminish the objections of the overworked undergraduate teacher who had not originally thought that such activities would be included in his duties This was particularly true of the basic science instructors Coloring the reluctance of this group was their inherent fear of disapproval when they appeared before clinicians The gradual fortification of the faculty with additional members and the inclusion in their initial interviews of an outline of responsibility to postgraduate education has overcome this problem At present, there is not a single member of any department of the medical school who does not willingly and frequently help with this form of teaching One basic science teacher has, on several occasions, stated that he has never had previously such an excellent opportunity to assay the results of his undergraduate teaching

The constant participation of basic science teachers along with clinical teachers in teaching teams, both in the circuit program and in short courses, has done much to eliminate the schism between basic scientists and practicing physicians It has vastly improved the morale of the basic science teachers by fostering a closer relationship with men who use their discoveries in daily practice This team association has also done much to improve the level of teaching by the clinician, who all too often is quite offhand in interpreting disturbed physiology and other basic phenomena if there be no one around to check this enthusiasm

The liberal use of "guest faculty members for participation in all short courses lessens the burden on our own faculty, but the local faculty assumes full responsibility for the circuit programs as well as for the clinical traineeships For the short courses, they assist with ward rounds, conferences, and panel discussions, participating only occasionally in didactic presentations Distinguished guest faculty members have always been used in this program as a means of supplementing our own staff and of increasing program appeal and effectiveness There is no question about the soundness and popularity of the practice among both our faculty and the enrollees

Self-analysis and Evaluation

The ultimate aim of postgraduate education today is the fostering of the best quality of medical care by each practicing physician It, therefore, behooves an alert administrator in this field to appraise or inquire into the character and type of practice in the region served He should learn of the needs and desires of his potential student body concerning program content, format, instructional staff, favorable dates for courses, and appropriate fees

One can immediately appreciate the need for perpetual self-analysis and evaluation as elements in the continuation of successful operation of a program of postgraduate medical education No medical administrator should be satisfied with organizing such a venture and then sitting back complacently to let it operate year after year without continuing study appraisal, evaluation, and improvement

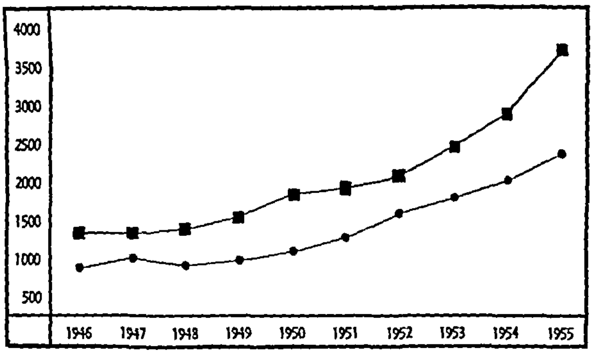

Fig 1—Graph showing summary of enrollment from 1946 through 1955 at University of Kansas School of Medicine The enrollment of physicians (circles) is compared to the total enrollment (squares)

The department has sought such information from its student body in several ways 1 Questionnaires are sent out by the medical society to individual practicing physicians inquiring about their own types of practice as well as about many of the common questions confronting a producer of postgraduate courses 2 Registration data (fig 1) are secured on each enrollee and tabulated annually, including city and state of practice, field of practice (fig 2), medical school, year of graduation, and distance traveled to attend program This tabulation is subjected to continuous analysis 3 An individual study of the patients seen and treated by a group of representative general practitioners holding appointments as medical school preceptors is currently being carried out with the assistance of our medical student preceptees 4 Each program produced is subjected to critical study by the submission to each enrollee of a questionnaire concerning the specific program, its content, format, teaching techniques, and fees and suggested improvements

Data on the 2,319 physicians enrolled in postgraduate courses in 1955-1956 show the type of information that is obtained from enrollment questionnaires A study of the geographical distribution revealed that 1,096 physicians were from Kansas, 1,211 from other states, 2 from territories of the United States, and 10 from foreign countries Data on distance traveled to attend courses during the same period showed that 328 physicians traveled less than 25 miles, 186 from 25 to 100, 256 from 100 to 200 miles, 360 from 200 to 300 miles, 157 from 300 to 500 miles, 96 from 500 to 1,000 miles, and 60 over 1,000 miles

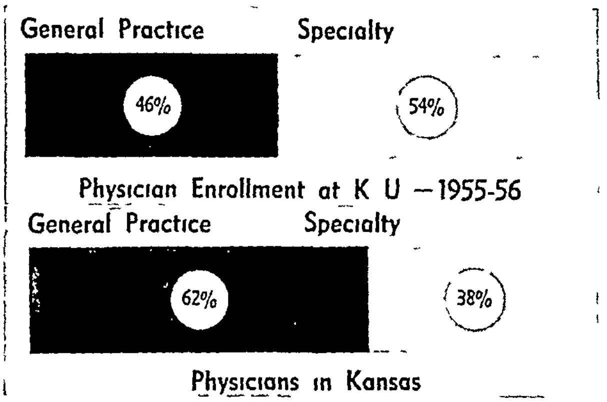

Fig 2—Graphs showing percentages of physicians in general and specialty practice enrolled in postgraduate courses at the University of Kansas in 1955-1956 compared to percentages of physicians in general and specialty practice in Kansas

Collection of registration data and 'postmortem' information on programs is routine and continuous The surveys of medical practice in our state, as well as the studies on the individual practitioner with regard to such factors as his training and his field of practice, are special projects to be repeated at suitable intervals (fig 3) *Securing such information is essential* to the success of a postgraduate program

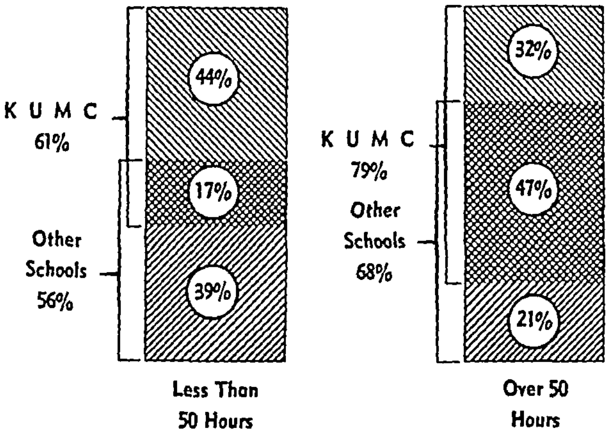

Fig 3—Graphs showing place of enrollment of physicians taking less than 50 hours and more than 50 hours of postgraduate work in 1953, 1954 and 1955

Physicians are compelled to attend continuation study exercises, an impelling conscience being the effective incentive Only the Academy of General Practice has had the courage to suggest more effective compulsion The postgraduate student must be attracted to a program and his interest must be captivated to hold him His body cannot be captured as can the undergraduate's The program must be sound, useful, and inspirational if he is to remain It must promise the same for the future if he is to return Programs must be planned carefully, promoted effectively, and produced well if they are to serve their purpose This requires constant study and re-study of one's own problems To date, there is no large and reliable clearing house of information or fostering influence to guide the school, department, or any other producer of postgraduate medical education Each must chart its own course

Future of Program

Looking to the future, we envision retention of the present administrative structure, with the program operated as a department in a medical school, with use of the same teaching staff and retention of close identity with the parent medical school Establishing a separate division or school would sacrifice something built deliberately—a teaching staff committed to all phases of medical education The close liaison with the state medical society has been a major factor in the growth and security of our program, and retention of this relationship is essential

Equally necessary is continued long-term planning of the programs of intermittent and short courses to fit the needs of the physicians of this region, with careful attention being given to curriculum material, effective methods of presentation, and selection of a competent faculty

One of the United States real contributions to medical education has been in the field of graduate medical education Residency training is a proved method of giving, at least temporarily, a high degree of professional medical competence The usual short and intermittent courses cannot be compared with it for effectiveness This observation leads to a desire to increase our clinical-traineeship teaching, simply because of the superiority of this method

Promoting the acceptance of a fourth phase of medical education as a reality and engaging in and assisting voluntary health organizations in health education are considered to be other important future objectives

We must continue the collection of data from registrants—the study of problems and practices of the student body This sort of research and critical analysis is, at present, the only means available for evaluation and improvement of the program Ultimate determination of whether a program is raising the level of medical care and inspiring the hoped-for response in the student body defies a direct approach Further research in methods and modalities of teaching should represent another field of study for a progressive program Increased use of television and the development of new home study courses and exploratory courses in yet untried fields represent further possibilities in development

Summary

The Kansas program of postgraduate medical education has, during the past 14 years, gained new vitality and purpose Most important in this change has been the association with the state medical society—members of which compromise the program's student body Next in importance has been recognition by the university and the medical school of their prime responsibility for this phase of medical education The school s acceptance took tangible form in the creation of a department of postgraduate medical education which gave the program administration, faculty, facilities, and a budget The department provided the remaining essentials—curriculum, teaching methods and self-analysis and evaluation

The future will be secure if sound educational policies based upon continuing critical self-appraisal are maintained Acceptance of the program is assured so long as the mutually profitable relationship with the student body exists

Types of Thyrotoxicosis —Thyrotoxicosis embodies three main components—thyrotoxic, mechanical and cardiac—which vary in importance in any individual case The thyrotoxic component includes all the manifestations of thyroid overactivity, the mechanical component consists of pressure effects exerted by the bulk of the goiter upon the trachea or oesophagus, and the cardiac component comprises auricular fibrillation and congestive heart failure Cases of thyrotoxicosis may be subdivided into primary and secondary types Primary thyrotoxicosis, or exophthalmic goiter, usually affects young women whose thyroid glands are believed to have been previously normal The clinical picture is almost wholly one of the thyrotoxic component The goiter is smooth, diffusely enlarged, symmetrical and seldom large, pressure effects upon the trachea or oesophagus are exceptional, hence there is no mechanical component In the absence of pre-existent rheumatic or other heart disease the cardiac component, as manifested by thyrotoxic auricular fibrillation and congestive heart failure, is very rare Secondary thyrotoxicosis, or toxic nodular goiter, on the other hand, affects middle-aged or elderly women who have often possessed a previously sim[illegible] goiter for many years With the passage of time the goiter has slowly enlarged, beco[illegible] nodular and asymmetrical Pressure upon, or deviation of, the trachea and oesophagus [illegible] border of the goiter may have descended into the thoracic inlet [illegible] often a marked feature The cardiac component is al[illegible] sh[illegible] fibrillation or congestive heart failure, but the thyrot[illegible] as [illegible] than in primary cases —L Martin, M D , F R C P , [illegible] Th[illegible] *Practitioner*, June, 1956

UNIVERSITY OF MICHIGAN PLAN FOR POSTGRADUATE MEDICAL EDUCATION

AN EXAMPLE OF THE POTENTIALITIES OF REGIONAL HOSPITAL–MEDICAL SCHOOL AFFILIATION

Harry A Towsley, M D, Ann Arbor, Mich

• *The best place for a physician to continue his education is in his own hospital, where he can assume a sincere obligation for his share of the training program The development and maintenance of a satisfactory graduate training program in the regional hospital by members of its own staff provide a continuous opportunity for intellectual stimulation It has been observed that practicing physicians in regional hospitals, through their repeated contacts with members of the faculty where there is a visiting program as provided by the University of Michigan, are more prone to utilize consultation, and such consultation, whether it be formal or informal, provides immeasureable education opportunities at all levels*

The faculty of the University of Michigan Medical School, in addition to its primary obligations to provide undergraduate medical education, to conduct research, and to care for the sick, is engaged in three major activities in the field of postgraduate medical education These are the extramural, circuit program, the intramural, refresher courses, and the program for affiliated hospitals In the order listed, each program provides increasing potentialities for continuing education for practicing physicians

Extramural and Intramural Programs

The extramural program is a combined project of the Michigan State Medical Society, the Michigan Department of Health, Wayne State University College of Medicine, and the University of Michigan Medical School Programs are arranged by the department of postgraduate medicine at the University of Michigan, utilizing the faculty members of the two medical schools Nineteen centers served by this program are located mainly in the rural areas of the state Teams of two to three faculty members present lectures on prearranged subjects in each center Where facilities permit and audiences desire, clinical conferences are held These programs provide a brief postgraduate educational experience twice yearly for approximately 800 physicians (fig 1)

The intramural program provides some 17 refresher courses at the University of Michigan in the various fields of medicine These courses are of three-days' to five days duration The average annual registration is approximately 900 physicians The opportunity for close intellectual exchange between teacher and practicing physician in these courses leaves little doubt as to the educational stimulation derived

Programs for Regional Affiliated Hospitals

The programs for affiliated regional hospitals in Michigan encompass three educational activities in 19 hospitals These activities include the residency program in 15 hospitals (see table), the two-year general practice program in 2 hospitals, and the program for general practice experience for undergraduate students in 2 hospitals The distribution of these hospitals is shown in figure 2

The potentialities for postgraduate medical education for the physicians comprising the attending staffs of these hospitals are broad and continuous They are in direct proportion to the physician s interest, enthusiasm, and perseverance in the conduct of successful training programs in the regional hospitals The basic objectives and method of conduct of the affiliated-hospital programs were clearly defined by Wilkinson,[1] who served as coordinator at the time of their inception However, to set forth more clearly the potentials for postgraduate education at the present time, a brief review of the method of operating is presented

Residency Program —Of the 15 hospitals participating in the residency program 3 are affiliated for residencies in internal medicine, 1 for surgery, 5 for medicine and surgery, and 6 for medicine, surgery, and obstetrics and gynecology, making a total of 32 affiliations in the three specialties A hospital must first obtain approval from the Council on Medical Education and Hospitals of the American Medical Association for the residency program for which it seeks affiliation Under the terms of affiliation, the hospital agrees to provide a minimum teaching program consisting of (1) teaching ward rounds of at least one-hours duration on the affiliated service five days weekly, (2) a weekly, radiologic, clinical, and clinicopathological conference, and (3) outpatient experience for the residents on the affiliated service The individuals responsible for the teaching programs on the affiliated service must be diplomates of their respective board or fellows of their respective specialty college

The medical school assists the regional hospital with its training program in two ways First, courses at the University of Michigan in the basic sciences and their clinical correlation are provided for the residents These courses vary according to the specialty affiliation

The surgical residents from hospitals with a three-year approved residency come to the university after two years in residency in the affiliated hospital Approximately half of each day for nine months is devoted to the review of the basic sciences as they may pertain to surgery, under the direction of the basic sciences faculty The second half of each day is occupied with the clinical correlation and application of the basic sciences This correlation, under the direc-

Professor of Pediatrics and Communicable Diseases and Associate Director of the Department of Postgraduate Medicine, University of Michigan Medical School

Read before the 53rd Annual Congress on Medical Education and Licensure Chicago, Feb 11, 1957 vated to hold him. His body cannot be captured as can the undergraduate's. The program must be sound, useful, and inspirational if he is to remain. It must promise the same for the future if he is to return. Programs must be planned carefully, promoted effectively, and produced well if they are to serve their purpose. This requires constant study and re-study of one's own problems. To date, there is no large and reliable clearing house of information or fostering influence to guide the school, department, or any other producer of postgraduate medical education. Each must chart its own course.

Future of Program

Looking to the future, we envision retention of the present administrative structure, with the program operated as a department in a medical school, with use of the same teaching staff and retention of close identity with the parent medical school. Establishing a separate division or school would sacrifice something built deliberately—a teaching staff committed to all phases of medical education. The close liaison with the state medical society has been a major factor in the growth and security of our program, and retention of this relationship is essential.

Equally necessary is continued long-term planning of the programs of intermittent and short courses to fit the needs of the physicians of this region, with careful attention being given to curriculum material, effective methods of presentation, and selection of a competent faculty.

One of the United States' real contributions to medical education has been in the field of graduate medical education. Residency training is a proved method of giving, at least temporarily, a high degree of professional medical competence. The usual short and intermittent courses cannot be compared with it for effectiveness. This observation leads to a desire to increase our clinical-traineeship teaching, simply because of the superiority of this method.

Promoting the acceptance of a fourth phase of medical education as a reality and engaging in and assisting voluntary health organizations in health education are considered to be other important future objectives.

We must continue the collection of data from registrants—the study of problems and practices of the student body. This sort of research and critical analysis is, at present, the only means available for evaluation and improvement of the program. Ultimate determination of whether a program is raising the level of medical care and inspiring the hoped-for response in the student body defies a direct approach. Further research in methods and modalities of teaching should represent another field of study for a progressive program. Increased use of television and the development of new home study courses and exploratory courses in yet untried fields represent further possibilities in development.

Summary

The Kansas program of postgraduate medical education has, during the past 14 years, gained new vitality and purpose. Most important in this change has been the association with the state medical society—members of which compromise the program's student body. Next in importance has been recognition by the university and the medical school of their prime responsibility for this phase of medical education. The school's acceptance took tangible form in the creation of a department of postgraduate medical education, which gave the program administration, faculty, facilities, and a budget. The department provided the remaining essentials—curriculum, teaching methods, and self-analysis and evaluation.

The future will be secure if sound educational policies based upon continuing critical self-appraisal are maintained. Acceptance of the program is assured so long as the mutually profitable relationship with the student body exists.

Types of Thyrotoxicosis.—Thyrotoxicosis embodies three main components—thyrotoxic, mechanical and cardiac—which vary in importance in any individual case. The thyrotoxic component includes all the manifestations of thyroid overactivity, the mechanical component consists of pressure effects exerted by the bulk of the goiter upon the trachea or oesophagus, and the cardiac component comprises auricular fibrillation and congestive heart failure. Cases of thyrotoxicosis may be subdivided into primary and secondary types. Primary thyrotoxicosis, or exophthalmic goiter, usually affects young women whose thyroid glands are believed to have been previously normal. The clinical picture is almost wholly one of the thyrotoxic component. The goiter is smooth, diffusely enlarged, symmetrical and seldom large, pressure effects upon the trachea or oesophagus are exceptional, hence there is no mechanical component. In the absence of pre-existent rheumatic or other heart disease the cardiac component, as manifested by thyrotoxic auricular fibrillation and congestive heart failure, is very rare. Secondary thyrotoxicosis, or toxic nodular goiter, on the other hand, affects middle-aged or elderly women who have often possessed a previously simple goiter for many years. With the passage of time the goiter has slowly enlarged, becoming nodular and asymmetrical. Pressure upon, or deviation of, the trachea and oesophagus is common and the lower border of the goiter may have descended into the thoracic inlet. The mechanical component is thus often a marked feature. The cardiac component is also common and shown as auricular fibrillation or congestive heart failure, but the thyrotoxic component is, as a rule, less evident than in primary cases.—L. Martin, M.D., F.R.C.P., The Treatment of Thyrotoxicosis, *The Practitioner,* June, 1956.

UNIVERSITY OF MICHIGAN PLAN FOR POSTGRADUATE MEDICAL EDUCATION

AN EXAMPLE OF THE POTENTIALITIES OF REGIONAL HOSPITAL-MEDICAL SCHOOL AFFILIATION

Harry A. Towsley, M.D., Ann Arbor, Mich.

• *The best place for a physician to continue his education is in his own hospital, where he can assume a sincere obligation for his share of the training program. The development and maintenance of a satisfactory graduate training program in the regional hospital by members of its own staff provide a continuous opportunity for intellectual stimulation. It has been observed that practicing physicians in regional hospitals, through their repeated contacts with members of the faculty where there is a visiting program as provided by the University of Michigan, are more prone to utilize consultation, and such consultation, whether it be formal or informal, provides immeasurable education opportunities at all levels.*

The faculty of the University of Michigan Medical School, in addition to its primary obligations to provide undergraduate medical education, to conduct research, and to care for the sick, is engaged in three major activities in the field of postgraduate medical education. These are the extramural, circuit program, the intramural, refresher courses, and the program for affiliated hospitals. In the order listed, each program provides increasing potentialities for continuing education for practicing physicians.

Extramural and Intramural Programs

The extramural program is a combined project of the Michigan State Medical Society, the Michigan Department of Health, Wayne State University College of Medicine, and the University of Michigan Medical School. Programs are arranged by the department of postgraduate medicine at the University of Michigan, utilizing the faculty members of the two medical schools. Nineteen centers served by this program are located mainly in the rural areas of the state. Teams of two to three faculty members present lectures on prearranged subjects in each center. Where facilities permit and audiences desire, clinical conferences are held. These programs provide a brief postgraduate educational experience twice yearly for approximately 800 physicians (fig. 1).

The intramural program provides some 17 refresher courses at the University of Michigan in the various fields of medicine. These courses are of three-days' to five-days' duration. The average annual registration is approximately 900 physicians. The opportunity for close intellectual exchange between teacher and practicing physician in these courses leaves little doubt as to the educational stimulation derived.

Programs for Regional Affiliated Hospitals

The programs for affiliated regional hospitals in Michigan encompass three educational activities in 19 hospitals. These activities include the residency program in 15 hospitals (see table), the two-year general practice program in 2 hospitals, and the program for general practice experience for undergraduate students in 2 hospitals. The distribution of these hospitals is shown in figure 2.

The potentialities for postgraduate medical education for the physicians comprising the attending staffs of these hospitals are broad and continuous. They are in direct proportion to the physician's interest, enthusiasm, and perseverance in the conduct of successful training programs in the regional hospitals. The basic objectives and method of conduct of the affiliated-hospital programs were clearly defined by Wilkinson,[1] who served as coordinator at the time of their inception. However, to set forth more clearly the potentials for postgraduate education at the present time, a brief review of the method of operating is presented.

Residency Program.—Of the 15 hospitals participating in the residency program 3 are affiliated for residencies in internal medicine, 1 for surgery, 5 for medicine and surgery, and 6 for medicine, surgery, and obstetrics and gynecology, making a total of 32 affiliations in the three specialties. A hospital must first obtain approval from the Council on Medical Education and Hospitals of the American Medical Association for the residency program for which it seeks affiliation. Under the terms of affiliation, the hospital agrees to provide a minimum teaching program consisting of (1) teaching ward rounds of at least one-hour's duration on the affiliated service five days weekly, (2) a weekly, radiologic, clinical, and clinicopathological conference, and (3) outpatient experience for the residents on the affiliated service. The individuals responsible for the teaching programs on the affiliated service must be diplomates of their respective board or fellows of their respective specialty college.

The medical school assists the regional hospital with its training program in two ways. First, courses at the University of Michigan in the basic sciences and their clinical correlation are provided for the residents. These courses vary according to the specialty affiliation.

The surgical residents from hospitals with a three-year approved residency come to the university after two years in residency in the affiliated hospital. Approximately half of each day for nine months is devoted to the review of the basic sciences as they may pertain to surgery, under the direction of the basic sciences faculty. The second half of each day is occupied with the clinical correlation and application of the basic sciences. This correlation, under the direc-

Read before the 53rd Annual Congress on Medical Education and Licensure, Chicago, Feb. 11, 1957.

tion of members of the clinical faculty, is carried out through clinical conferences, lectures, demonstrations, and bedside teaching The remaining three months of the year, the residents may elect to spend their time in one of the surgical specialties Upon completion of the year at the University Hospital, residents return as chief residents to their hospitals for the third and final year of training The year at the medical school is credited as one of the two years, over and above the three years of residency, required of group 2 candidates for certification by the American Board of Surgery

Currently, residents in internal medicine spend nine months of the second of their three years in a similar course, with the choice of electing to spend the remaining three months in one of the medical specialties at the university Also, residents in obstetrics and gynecology have had a special six-months' course in basic sciences pertaining to that specialty and a similar experience in correlation and application directed by the clinical faculty in that field All residents in these courses are expected to attend the major teaching conferences held by the clinical departments of the medical school in the specialty for which they are affiliated

Visiting Program —The second method by which the university assists the affiliated hospital is by providing a regularly scheduled visiting program by members of the faculty The purpose of these visits is to aid in the teaching and to evaluate critically the training program in each hospital Six faculty visits are made annually in the specialty for which the affiliation has been made Hospitals affiliated for two specialties are visited 12 times annually Those affiliated for three are visited 18 times each year Prior to 1954, nine visits were made annually by the faculty for each specialty affiliation When the undergraduate enrollment was increased to 200 students in each class, however, it became necessary to reduce the visits to the present number

Each member of the faculty visiting the affiliated hospitals is prepared to present a didactic lecture on a prearranged subject in his field of medicine and to conduct a clinical conference on patients presented by members of the house staff Both the house and attending staffs are urged to be present Notification of these scheduled meetings is made well in advance by the education committee in each hospital either by postal card, hospital news letter, or bulletin board

In addition, the faculty representative makes teaching ward rounds with the residents, interns, or students and any member of the staff who wishes to attend He also reviews records of patients for content and thoroughness of study and holds general conferences with the house staff, during which he discusses their teaching program or any other items within his scope that they may wish to consider After his visit, each faculty representative makes a written report to the chief of the service that he represents and to the coordinator of the program These reports include his general observations, the number of members of the active and house staffs attending the conference, an evaluation of the degree of interest and enthusiasm on their part, a report on the general character and quality of patient records, and especially his evaluation of the training program

In annual visits to these hospitals, the coordinator of these programs holds a conference with the interns and residents for the purpose of obtaining their evaluation of the training program With this information and the critical evaluation submitted by each of the faculty visitors during the year, a conference is held with the education committees, and attempts are made to correct any weaknesses or omissions found in the teaching program Further, a day-long conference is held at the university once each year for all the education committees of the hospitals and directors of each affiliated hospital with the chairmen of the clinical departments of the medical school or their representatives In these conferences, the mutual problems in the over-all programs are considered

Program for Training in General Practice —The program for training in general practice is specifically designed to provide at least two years of training for recent graduates who want to enter general practice It combines teaching in the environment of a university hospital with the practical approach to common medical problems as they are found in a community hospital Mercy Hospital, Benton Harbor, and Midland Hospital, Midland, both staffed by practicing physicians representing both the specialties and general practice, are affiliated for this program To become affiliated, a hospital must possess, in addition to the physical qualifications to meet the requirements of the "Essentials of an Approved Internship,' - a medical staff that will agree to provide the minimum teaching program outlined above in the discussion of residency affiliation

In an attempt to solve the problem of the distribution of doctors to the less urban communities in the state, hospitals located in rural communities are selected for this program The university assists these hospitals by selecting from 10 to 12 interns annually Each intern spends six months of each of the two years at the University Hospital and six months of each of the two years in one of the affiliated hospitals as an intern the first year and as an assistant resident the second In this manner, each affiliated hospital is furnished with at least two interns and two assistant residents at all times The university also provides a teaching resident from the medical and surgical services of the University Hospital on a rotation basis of three to six months The teaching resident, in addition to helping with patient care, assists with the organiza tion of the teaching program by planning with the education committee of the affiliated hospital the rotation of interns and residents and the scheduling of ward rounds and conferences, insuring that members of the attending staff meet their scheduled teaching obligations He also shares in the teaching program

Further assistance is provided to these hospitals by the visiting program and by evaluation conferences, as described in the discussion of residency affiliation, except that visits to these hospitals are made nine times each year by teams of two faculty members representing the four major specialties The conferences with the coordinator are held usually twice annually until the program is established James Decker Munson Hospital, Traverse City, formerly affiliated for rotation of interns, now procures its own interns on the matching plan At its own request and expense, it continues to receive the visiting program from the university

Program for Student Experience in General Practice—The program for student experience in general practice is a relatively new venture at the university, having been established two years ago The senior year in the medical school is divided into five nine-week sections, one of these sections being a vacation period The majority of students elect to obtain experience by serving as externs in many hospitals during their free period This program is made available especially for those who are interested in general practice

Two small community hospitals, Emma L Bixby, Adrian, with a 60-bed capacity, and Memorial Hospital, Owosso, with a 120-bed capacity, in the rural areas of the state were selected to provide this experience The staff in each hospital is composed of doctors both in general practice and in the specialties Under the terms of affiliation, the staffs of these hospitals agree to provide supervised educational and clinical experience and to conduct a teaching program for students

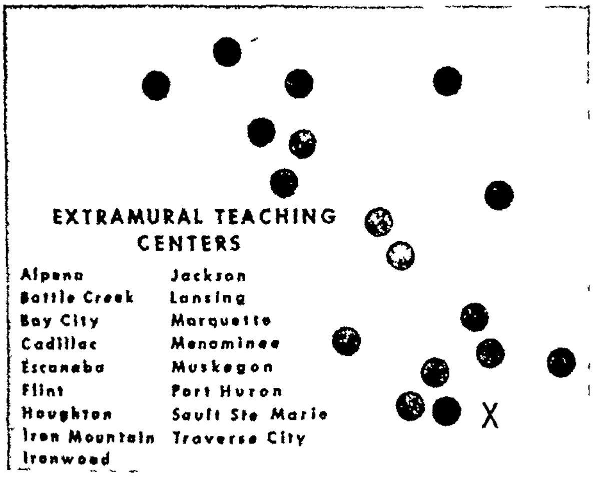

Fig 1—Map of Michigan showing locations of extramural teaching centers in relation to location of the University of Michigan (X)

The university assists these hospitals by providing 12 scheduled faculty visits annually by representatives from the four major specialties The content of these visits is similar to that in the residency and general practice programs

The visiting programs to each hospital require three to five hours of the faculty member's time, excluding travel A minimum of one and a half to two hours is devoted to a combined lecture and clinical conference The remaining time is occupied with ward rounds and conferences with the residents, interns, or students

Statistics and Finances of All Programs—For all of the programs in the 19 hospitals, the faculty averages 264 visits and travels more than 26,000 miles each year Over a five-year period, an annual average of 65 visits from senior clinical instructors, 99 from assistant professors, 73 from associate professors, and 17 from professors have been made under these programs All these persons are full-time or geographical full-time members of the faculty of the medical school

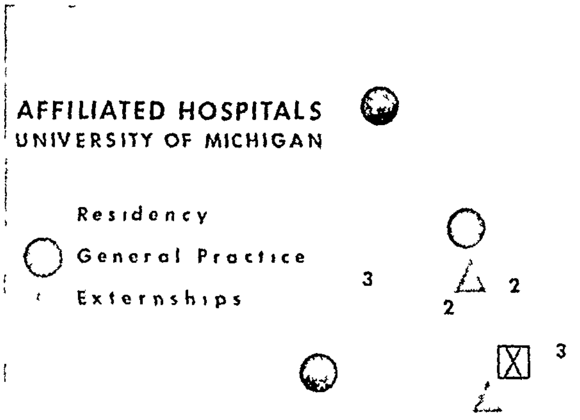

Fig 2—Map of lower peninsula of Michigan showing locations of hospitals affiliated with the University of Michigan for various programs Square with X superimposed denotes the location of the University of Michigan and of an affiliated hospital in the same community

The financial support of these programs has an indirect relationship to their recognized potential for postgraduate education The W K Kellogg Foundation with a very generous grant, supported these programs for the first five years of their operation They have been supported for the last five years by the affiliated hospitals and by general funds from the university The hospitals carry about one-third of the cost It is of particular interest that the members of the attending staffs, through contributions to the regional hospitals provide about 75% of the funds coming to the university from the hospitals for support of the program The amount contributed by the staff members in the affiliated hospitals is sufficient to cover travel and hotel expenses of faculty members, faculty honoraria, and part of the administrative expense The staff members, by contributing to these funds are, in effect, paying for their own opportunity for continuing education provided by these programs and, at the same time, supporting materially the education of residents and interns

Potentialities for Postgraduate Education

The potentialities for postgraduate medical education, as exemplified in these programs, may be divided into two general categories—the direct and the indirect

Direct Potential—The direct potential for postgraduate education, if measured in terms of the number of hours of lectures and conferences provided by medical tion of members of the clinical faculty, is carried out through clinical conferences, lectures, demonstrations, and bedside teaching The remaining three months of the year, the residents may elect to spend their time in one of the surgical specialties Upon completion of the year at the University Hospital, residents return as chief residents to their hospitals for the third and final year of training The year at the medical school is credited as one of the two years, over and above the three years of residency, required of group 2 candidates for certification by the American Board of Surgery

Currently, residents in internal medicine spend nine months of the second of their three years in a similar course, with the choice of electing to spend the remaining three months in one of the medical specialties at the university Also, residents in obstetrics and gynecology have had a special six-months course in basic sciences pertaining to that specialty and a similar experience in correlation and application directed by the clinical faculty in that field All residents in these courses are expected to attend the major teaching conferences held by the clinical departments of the medical school in the specialty for which they are affiliated

Visiting Program —The second method by which the university assists the affiliated hospital is by providing a regularly scheduled visiting program by members of the faculty The purpose of these visits is to aid in the teaching and to evaluate critically the training program in each hospital Six faculty visits are made annually in the specialty for which the affiliation has been made Hospitals affiliated for two specialties are visited 12 times annually Those affiliated for three are visited 18 times each year Prior to 1954, nine visits were made annually by the faculty for each specialty affiliation When the undergraduate enrollment was increased to 200 students in each class, however, it became necessary to reduce the visits to the present number

Each member of the faculty visiting the affiliated hospitals is prepared to present a didactic lecture on a prearranged subject in his field of medicine and to conduct a clinical conference on patients presented by members of the house staff Both the house and attending staffs are urged to be present Notification of these scheduled meetings is made well in advance by the education committee in each hospital either by postal card, hospital news letter, or bulletin board

In addition, the faculty representative makes teaching ward rounds with the residents, interns, or students and any member of the staff who wishes to attend He also reviews records of patients for content and thoroughness of study and holds general conferences with the house staff, during which he discusses their teaching program or any other items within his scope that they may wish to consider After his visit, each faculty representative makes a written report to the chief of the service that he represents and to the coordinator of the program These reports include his general observations, the number of members of the active and house staffs attending the conference, an evaluation of the degree of interest and enthusiasm on their part, a report on the general character and quality of patient records, and especially his evaluation of the training program

In annual visits to these hospitals, the coordinator of these programs holds a conference with the interns and residents for the purpose of obtaining their evaluation of the training program With this information and the critical evaluation submitted by each of the faculty visitors during the year, a conference is held with the education committees, and attempts are made to correct any weaknesses or omissions found in the teaching program Further, a day-long conference is held at the university once each year for all the education committees of the hospitals and directors of each affiliated hospital with the chairmen of the clinical departments of the medical school or their representatives In these conferences, the mutual problems in the over-all programs are considered

Program for Training in General Practice —The program for training in general practice is specifically designed to provide at least two years of training for recent graduates who want to enter general practice It combines teaching in the environment of a university hospital with the practical approach to common medical problems as they are found in a community hospital Mercy Hospital, Benton Harbor, and Midland Hospital, Midland, both staffed by practicing physicians representing both the specialties and genera practice, are affiliated for this program To become affiliated, a hospital must possess, in addition to the physical qualifications to meet the requirements of the "Essentials of an Approved Internship,'[2] a medical staff that will agree to provide the minimum teaching program outlined above in the discussion of residency affiliation

In an attempt to solve the problem of the distribution of doctors to the less urban communities in the state, hospitals located in rural communities are selected for this program The university assists these hospitals by selecting from 10 to 12 interns annually Each intern spends six months of each of the two years at the University Hospital and six months of each of the two years in one of the affiliated hospitals as an intern the first year and as an assistant resident the second In this manner, each affiliated hospital is furnished with at least two interns and two assistant residents at all times The university also provides a teaching resident from the medical and surgical services of the University Hospital on a rotation basis of three to six months The teaching resident, in addition to helping with patient care, assists with the organiza tion of the teaching program by planning with the education committee of the affiliated hospital the rotation of interns and residents and the scheduling of ward rounds and conferences, insuring that members of the attending staff meet their scheduled teaching obligations. He also shares in the teaching program.

Further assistance is provided to these hospitals by the visiting program and by evaluation conferences, as described in the discussion of residency affiliation, except that visits to these hospitals are made nine times each year by teams of two faculty members representing the four major specialties. The conferences with the coordinator are held usually twice annually until the program is established. James Decker Munson Hospital, Traverse City, formerly affiliated for rotation of interns, now procures its own interns on the matching plan. At its own request and expense, it continues to receive the visiting program from the university.

Program for Student Experience in General Practice.—The program for student experience in general practice is a relatively new venture at the university, having been established two years ago. The senior year in the medical school is divided into five nine-week sections, one of these sections being a vacation period. The majority of students elect to obtain experience by serving as externs in many hospitals during their free period. This program is made available especially for those who are interested in general practice.

Two small community hospitals, Emma L Bixby, Adrian, with a 60 bed capacity, and Memorial Hospital, Owosso, with a 120-bed capacity, in the rural areas of the state were selected to provide this experience. The staff in each hospital is composed of doctors both in general practice and in the specialties. Under the terms of affiliation, the staffs of these hospitals agree to provide supervised educational and clinical experience and to conduct a teaching program for students.

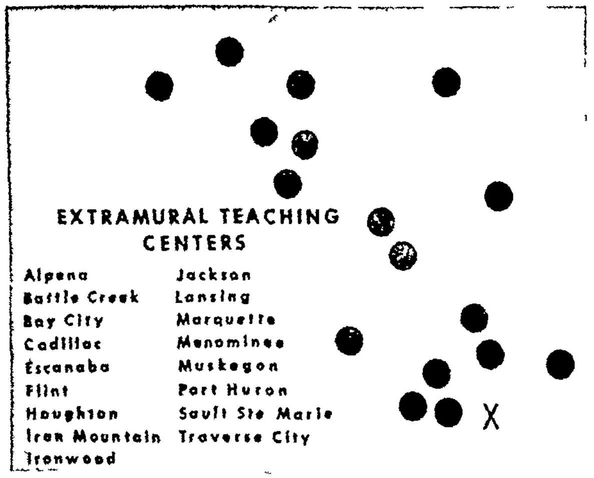

Fig 1.—Map of Michigan showing locations of extramural teaching centers in relation to location of the University of Michigan (X).

The university assists these hospitals by providing 12 scheduled faculty visits annually by representatives from the four major specialties. The content of these visits is similar to that in the residency and general practice programs.

The visiting programs to each hospital require three to five hours of the faculty member's time, excluding travel. A minimum of one and a half to two hours is devoted to a combined lecture and clinical conference. The remaining time is occupied with ward rounds and conferences with the residents, interns, or students.

Statistics and Finances of All Programs.—For all of the programs in the 19 hospitals, the faculty averages 264 visits and travels more than 26,000 miles each year. Over a five-year period, an annual average of 65 visits from senior clinical instructors, 99 from assistant professors, 73 from associate professors, and 17 from professors have been made under these programs. All these persons are full-time or geographical full-time members of the faculty of the medical school.

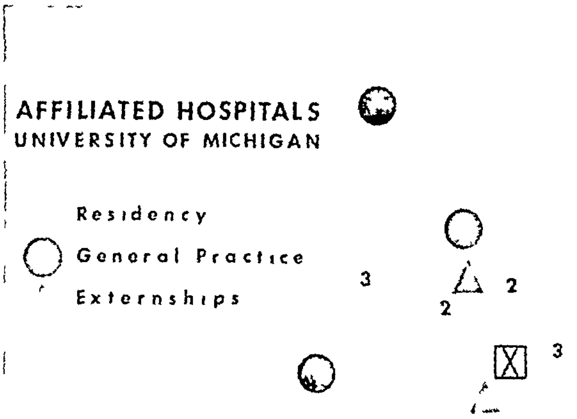

Fig 2.—Map of lower peninsula of Michigan showing locations of hospitals affiliated with the University of Michigan for various programs. Square with X superimposed denotes the location of the University of Michigan and of an affiliated hospital in the same community.

The financial support of these programs has an indirect relationship to their recognized potential for postgraduate education. The W K Kellogg Foundation, with a very generous grant, supported these programs for the first five years of their operation. They have been supported for the last five years by the affiliated hospitals and by general funds from the university. The hospitals carry about one-third of the cost. It is of particular interest that the members of the attending staffs, through contributions to the regional hospitals, provide about 75% of the funds coming to the university from the hospitals for support of the program. The amount contributed by the staff members in the affiliated hospitals is sufficient to cover travel and hotel expenses of faculty members, faculty honoraria, and part of the administrative expense. The staff members, by contributing to these funds are, in effect, paying for their own opportunity for continuing education provided by these programs and, at the same time, supporting materially the education of residents and interns.

Potentialities for Postgraduate Education

The potentialities for postgraduate medical education, as exemplified in these programs, may be divided into two general categories—the direct and the indirect.

Direct Potential.—The direct potential for postgraduate education, if measured in terms of the number of hours of lectures and conferences provided by medical school faculty members who have gained recognition in their special field of interest, would provide to the physicians in hospitals affiliated for one residency program 12 hours of postgraduate experience each year, to those in hospitals affiliated for two residency programs, 24 hours, and to those in hospitals affiliated for three residency programs, 36 hours. Physicians comprising the staff in hospitals affiliated for general practice training would receive approximately 18 hours of direct postgraduate education in the four major specialties, while staff members in hospitals affiliated for the student program are provided 24 hours of postgraduate education opportunity in the four major specialties.

It is estimated that approximately 1,500 physicians, representing the combined attending staffs of the 19 affiliated hospitals, would have the opportunity of receiving from 12 to 36 hours of postgraduate education annually in these programs. Actually, over the past five years, there has been an annual average attendance of 600 physicians. Of particular interest in regard to attendance is the fact that close to 75% of the available staff members in the more isolated rural hospitals exhibit a keen interest in postgraduate medical education, as manifested by their continued attendance at these functions.

Clinical conference teaching is generally regarded as far more stimulating and rewarding than the usual didactic lecture, particularly when the clinical material presented involves the patients in the doctor's own hospital. Unfortunately, all of the affiliated hospitals do not take full advantage of this method of teaching during each visit. In those hospitals, the potential for postgraduate education to the staff is reduced.

Indirect Potential.—The indirect opportunities for the continuation of professional growth for the practicing physicians in the regional hospitals are available in a number of ways. For example, the resident who has attended the program on the basic sciences and its combined clinical correlation and has taken advantage of the many teaching conferences available to him in his specialty at the university returns to his hospital with the knowledge of new diagnostic and therapeutic measures and new laboratory procedures, which he can disseminate to the members of the staff through conferences, ward rounds, and daily contacts.

The same may be said of the intern in the general practice program when he returns to the affiliated hospital for his second tour of duty and of the teaching resident who carries with him the teaching of the department in which he had his training at the university. To a far lesser degree, the medical student, with his recently acquired knowledge from the various departments in the medical school, may contribute in a similar fashion.

The development and maintenance of a satisfactory graduate training program in the regional hospital by members of its own staff provide a continuous opportunity for intellectual stimulation. Those who take the responsibility for teaching ward rounds, of necessity, are stimulated to peruse more critically the medical literature in the attempt to teach in a creditable manner. The repeated attendance and participation by the staff members in the teaching functions within their own hospital, such as clinical, clinicopathological, and x-ray conferences and journal club, provide unlimited potentialities to the practicing physician for continuation of his education, particularly when these functions are carried out as teaching exercises. The presence of a resident, intern, or student who is given the opportunity to discuss the differential diagnosis with the practicing physician at the bedside serves as a stimulus for more thorough study of the patient's problems, thus reducing the possibility of error in diagnosis and treatment.

In those hospitals with good teaching programs for the house staff, there appears to be a much freer use of consultation. Whether they be formal or informal, such consultations provide immeasurable education opportunities at all levels. It has been observed that practicing physicians in regional hospitals, through their repeated contacts with members of the faculty through the visiting program, are more prone to call faculty members in consultation for their difficult problems.

It has been repeatedly stated that the best place for a physician to continue his education is in his own hospital. This is true as long as he maintains an open, inquiring, critical mind and a keen interest in the progress of the science of medicine. This opportunity is greatly enhanced if his hospital is charged with the responsibility of providing a satisfactory training experience for residents, interns, or medical students, particularly if that obligation is discharged with pride in the products of its efforts.

The potential is further enhanced if the physician himself assumes a sincere obligation for his share of the training program offered by his hospital. Whether it be teaching at the bedside or in the scheduled conferences or directing journal club, adding his bit to the discussion will be stimulating and rewarding in that the knowledge gained therefrom will sooner or later be of benefit to his patients. In those hospitals where an honest and sustained effort to provide the best possible training program for the house staff exists, the practicing physician will find an unequaled opportunity for continuation of his own education.

Without the support of a university administration and a medical faculty dedicated to the belief that a doctor's education should not end with graduation from medical school or at the end of his internship or residency and without donation of time by the practicing physicians in the affiliated hospitals for educational programs for residents, interns, or medical students, postgraduation education opportunities for the less motivated practicing physician will not exist in his own hospital, where it is ripe for his taking. It is believed that the regional hospital–medical school programs offer the practicing physician an unequaled potential for continuation education.

NEW YORK UNIVERSITY PLAN

AN EXAMPLE SHOWING THE POTENTIALITIES OF REGIONAL HOSPITAL–MEDICAL SCHOOL AFFILIATION

Charles F Wilkinson Jr, M D, New York

• *The plan of having regional hospitals affiliated with university medical schools has certain advantages In the present instance, six hospitals are so affiliated, they are not limited by state lines, but by considerations of commuting distance The teaching plan is formulated and implemented by a local educational committee made up of the directors of the hospital's departments of surgery, medicine, obstetrics and gynecology, and pathology, with the assistance of other physicians of the staff the hospital also recruits and appoints interns and residents The university center supplies both administrative guidance and instructional resources, with emphasis on a sound house staff program and a minimum of lectures to large audiences The test for success in such a plan is the continued willingness of medical schools to participate and of the regional hospitals to bear most of the expense*

It is probably of some significance that eight years ago I presented a paper, "The Utilization of Regional Hospitals for Medical Education"[1] to this congress Now I have been asked to discuss the potentialities of such a program After eight years, this significance is twofold 1 Many persons are still interested in regional hospital–medical school affiliation 2 We still wonder what the potentialities are and, I presume, how we can measure them

Since I have been asked to discuss the potentialities within the framework of the New York University program, perhaps I should first describe the plan, although this could be done more adequately by my friend and colleague, Dr Clarance E de la Chapelle Since going to the New York University Post-Graduate Medical School, I have, on occasion, visited the regional hospitals as do other members of the professorial staff, but I have had no responsibility in the administration of the plan Thus, my comments might be considered the 'worm's-eye view, that is, the one of the full-time professor

Original Program

The New York University–regional hospital program, like so many of the regional programs, was made possible, at the start, by a grant from the W K Kellogg Foundation[2] It has, like most of these programs, undergone a series of changes and modifications so that, in its present form, it represents a compromise between what the program director, the affiliated hospital, and the faculty believe to be ideal and what is practical That the program exists at all today means to me that it cannot be too far from any of these three ideals

At the start, New York University had an advantage (at least it was considered by some as such) in not being a state university, and, therefore, it could operate across state lines I should add that here the so-called advantage ended It did not extend to such base and mundane things as the budget or faculty salaries The original description of the program[3] stated that it was intended that, by affiliation, the New York University College of Medicine would affiliate with selected hospitals in the suburbs, in small towns, and even in rural communities The members of the resident staffs of the hospitals would have the privilege of spending an academic year at the medical school, during which time they would participate in basic science or graduate courses applicable to their particular field of residency The basic science courses were taken on a part-time or a full-time basis, the graduate courses were taken full-time No tuition was charged, but the affiliated hospital was made responsible for the candidate's maintenance, whether the institution was within commuting distance or not

The members of the attending staffs of these hospitals, especially the younger men, had the opportunity to continue their own education by returning for ward work or continuation courses in the medical school and by the visits of faculty members to the hospitals The hospitals cooperating in the plan fulfilled all the requirements of the American College of Surgeons and, in addition, maintained an educational program outlined by the medical school

It was thought that the establishment of such a system of hospitals associated with a large medical center, with their teaching supervised by the medical school, would improve the quality of medical care and provide substantial broadening of the opportunities present for physicians to obtain graduate and postgraduate medical education

In 1948, the merger of the New York University College of Medicine and the New York Post-Graduate Medical School and Hospital had been effected, and the New York University–Bellevue Medical Center was established After this merger, the Division of Affiliated and Regional Hospitals was formed and placed, for administrative purposes, in the postgraduate medical school, but it was able to call on the faculties of both the college of medicine and the postgraduate medical school for periodic visits to the regional hospitals

By 1949, there were 10 affiliated hospitals in four states, with a total of some 2,500 beds (fig 1) There were salaried coordinators at each of the affiliated hospitals These coordinators were usually young men who had just entered practice They devoted from one-third to one-half of their time in arranging the educational program at the hospital and supervising the intern and resident training programs As the

Professor and Chairman Department of Medicine, New York University Post-Graduate Medical School

Read before the 53rd Annual Congress on Medical Education and Licensure, Chicago Feb 11, 1957 requirements of their practices became more demanding, they turned their jobs over to younger men and went on to equally important, but somewhat less active positions in the program This plan had the additional advantage of enabling desirable young men to start in a community with a small stipend that would help pay the office rent until their practices were established

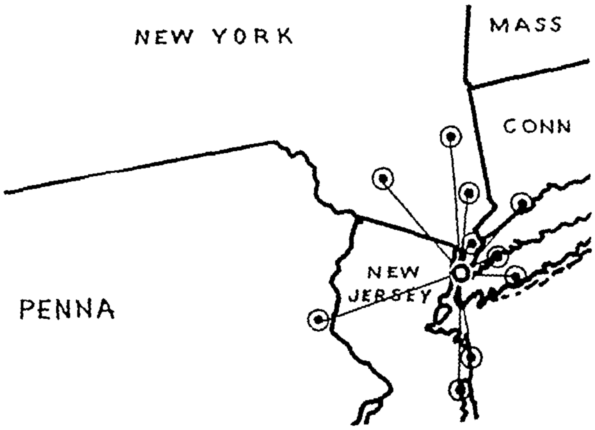

Fig 1—Dots show the geographical distribution of the 10 hospitals affiliated with the New York University–regional hospital plan in 1949

Present Program

At the present time, active membership in the regional hospital plan is limited to six hospitals[4] There are three levels of membership, designated as first, second, and third year A faculty representative visits the hospital in the first-year group two days a week during the academic year In the second year, visits are made weekly and in the third year biweekly After three years of active membership, a member hospital may continue its affiliation as a graduate hospital Faculty visits are then made on request

Faculty visits are dependent upon the needs of the various departments of the member hospital The making of a minimum number of planned presentations to large audiences is the rule Both the major specialties and the subspecialties are represented by the visiting faculty members No rigid schedule is followed as to the number of visits made to any department

In order to carry out successfully the regional hospital plan, it became apparent that unanimity of agreement on the part of the member hospital staffs as to the purpose of the plan was absolutely necessary Where there existed a misunderstanding in this regard, the regional program did not succeed to the same degree as it did where the active attending staff were unanimous in their desire for affiliation

In the present regional hospital plan, the center makes it clear to the member hospitals that there are many and varied opportunities for mutual discussion of problems By consultations with the administrative officers of the plan, considerable help is available to the local teaching program For example, members of the hospital staffs may come to the medical center and draw on the academic experience of the faculty as well as attend clinics, conferences, and seminars It is the policy of the administration of the regional hospital plan to emphasize these hitherto unused resources

The new plan does not provide for a local coordinator Experience gained from the old plan indicated that such a key figure in the operation of the hospital program should have some voice in making policy in the hospital The common lack of seniority of the coordinator interfered seriously with the implementation of the policies and programs he proposed

In the new plan, each member hospital forms a committee that is responsible for formulating and implementing a training program This educational committee is made up of the directors of the departments of surgery, medicine, obstetrics and gynecology, and pathology, with the assistance of other physicians of the staff One member of the committee acts as a liaison officer between the hospital and the center

Interns and residents are recruited and appointed by the member hospital The medical center requires, however, that the hospital be approved for intern or resident training by the Council on Medical Education and Hospitals of the American Medical Association The medical center does not assume responsibility for the recruitment or the appointment of interns and residents, nor is it responsible for maintaining or seeking approval for intern and resident training in a member hospital Rotation of residents between a member hospital and the center is not a part of the new program

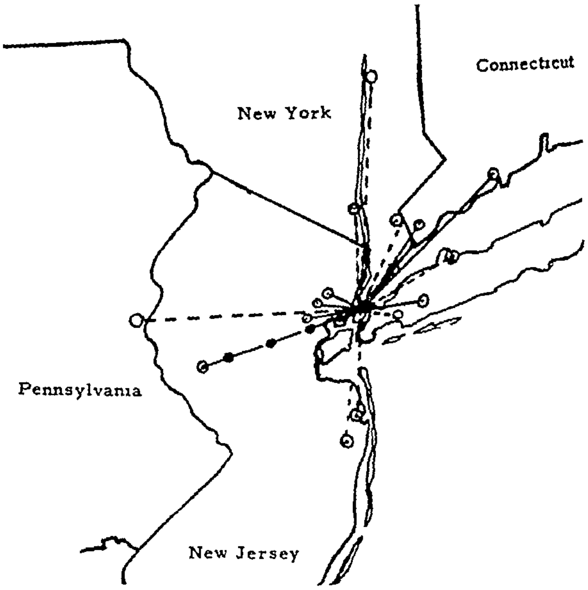

Fig 2—Dots show the geographical location of the hospitals presently affiliated (solid line) and those affiliated in the past (broken line) The one hospital indicated by a broken line and dots is Hunterdon Medical Center, Flemington, N J, and is considered in a separate category from the others

In order to minimize the nonproductive time consumed in travel, the geographical location of the regional hospitals participating in the new plan is limited to a radius of approximately 50 miles from the medical center

It is obvious that the outline I have presented of the New York University–regional hospital plan has been sketchy, but it will, I believe, serve the purpose of the symposium on postgraduate medical education Figure 2 shows what communities have had or do have hospitals participating in the plan

Potentialities and Success of Plan

What are the potentialities of this regional hospital–medical school affiliation? How can we evaluate success or lack of it? The potentialities appear to be as great as the vision and imagination of those administering and participating in the plan Ideally, any member hospital could eventually have superior local self-education for its staff, guided by the medical center Because of its educational program, the hospital should be more attractive to interns and residents, and a sound house-staff program should add stature to the continuing educational program of the visiting staff Because of an affiliation with the medical center, a hospital should have ready advice and consultation on matters ranging from diagnosis and therapy to new laboratory techniques and even hospital management Ultimately the regional hospital would be as much a part of the medical center as any ward geographically located in the center However, men being as they are, I do not expect perfection, but something less

It would be helpful if one could measure this degree of success Can this be done? To date, I know of no way to titrate these programs with any degree of accuracy Many of us have a feeling that they are more, rather than less, successful Members of the regional hospital staffs apparently feel that they are worthwhile and that the general level of medical practice in their hospital has been elevated

Some of us on the faculty feel, however, that our purpose would be better served if the affiliated hospitals were kept at a constant level of participation rather than at the step-like dissociation as in the present plan

From my own point of view, I hated to see the idea of the coordinator abandoned It had been my experience that it was easier to work through a coordinator than through a committee, but, as I pointed out earlier, my administrative experience was in a different part of the United States, and I cannot speak with any firsthand knowledge of the administrative problems associated with the current New York University–regional hospital program I can assure you that I have enjoyed my visits to the regional hospitals and that I have been impressed by the excellence of their training programs as well as by the standard of the medical care practiced in them

To me, the most significant fact is that the various hospitals in the regional plan of New York University pay for 80% or more of the cost of the program In other words, the regional hospitals want the program enough to pay their way On the side of the medical school, there is still enthusiasm on the part of some of us on the faculty and resigned acquiescence on the part of others, although I know of no active opposition

It would appear then, that, while not perfect, the New York University–regional hospital plan is here to stay It will, undoubtedly undergo other modifications in the future and may some day come even closer to the ideal of the medical center as an integral and vital part of the region it serves

Acute Nephritis —When clinically apparent the mode of presentation in acute nephritis is extremely variable The onset may be sudden or insidious, and may accompany, or follow after an interval the signs of an acute infection in some other part of the body, usually a hæmolytic streptococcal infection in the upper respiratory tract Broadly speaking the onset tends to be abrupt in children, and the signs of nephritis are then apt to be intermingled with, or even over-shadowed by those of the primary infection In adults the so called latent interval is often longer, and apart from initial malaise, the early signs of nephritis may be confined to urinary changes which, however, may be quite marked But both in children and in adults acute nephritis may be ushered in by any one, or any combination of its cardinal features—bloody and scanty urine, with or without frequency, urgency, lumbar aching and pain, and, in children, abdominal pain and vomiting—œdema, especially, and almost invariably, puffiness of the eyelids and face on waking in the morning, and, in those who remain ambulant, swelling of the feet and ankles—cardiovascular signs such as headache, vomiting convulsions and coma In cases of war nephritis dyspnœa was a very common presenting symptom though then rarely met with in civilians My impression is that dyspnœa is now more frequently seen as a presenting sign in civilians Unquestionably hæmaturia and œdema are the two most striking and common initial clinical signs in acute nephritis and it is of interest to note that over the years their relative prominence as presenting features has apparently been reversed — A A Osman, F R C P, Acute Nephritis, *The British Journal of Clinical Practice*, September, 1956

ESSENTIALS OF A RESIDENCY IN GENERAL PRACTICE

C. Wesley Eisele, M.D., Denver

• *There is evidence of a distinct upsurge of interest in the practice of general medicine. In the whole nation, 64% of all physicians in private practice are either general practitioners or part time specialists. To satisfy the increasing demand for advanced training in general practice, more and better residencies in this field must be offered. Such a residency should be a minimum of two years, must be equivalent in standards and prestige to a specialty residency, and must be primarily of educational value to the resident rather than a service to the hospital.*

A growing interest in the training of young physicians for general practice has become apparent in many quarters, and a panel on this subject at the annual meeting of the Advisory Board for Medical Specialties is particularly significant and heartening. This increasing interest seems to parallel a renewed conviction that the position of the general practitioner in American medicine is secure.

An organized general practice residency has been offered at the University of Colorado School of Medicine since 1948. Material for this paper has been drawn from experience with this program, experience that was recently crystallized by an analysis of questionnaires returned by former residents. The annual reports of the Council on Medical Education and Hospitals of the American Medical Association, publications of the Bureau of Medical Economic Research of the American Medical Association and brochures from many general practice residency programs have also been freely used.

A decade or so ago, there was a common belief that advances in knowledge and in technical developments would soon make the general practice of medicine untenable and it would become a relic of the past, but the expected demise of the general practitioner has not come to pass. On the contrary, a distinct upsurge of interest in this type of practice may be observed among superior young physicians. There continue to be more general practitioners in the United States than the total of all specialists combined, and there are more young physicians in general practice than in all the specialties combined. The American Academy of General Practice, although one of the youngest medical societies, is larger than any national specialty society. And a sizable proportion of the current generation of medical graduates continues to choose general practice in preference to a specialty. Tables 1, 2, and 3 present data in support of these statements.

The studies of Dickinson[1] and the Bureau of Medical Economic Research of the American Medical Association (table 1) show that general practitioners constitute the great majority of physicians in active private practice (72%) in cities with populations of 10,000 or less (12,829 communities). An additional 17% classify themselves as part-time specialists—physicians who are usually more closely akin to the general practitioner than to the full-time specialist. Even in cities with populations of 100,000 or more, 40% of the physicians are general practitioners and an additional 12% are part-time specialists. In the whole nation, 64% of all physicians in active private practice are either general practitioners or part-time specialists. The age distribution of physicians in active private practice (table 2) indicates that general practitioners as a group are significantly younger than either full time or part-time specialists.

Current generations of senior medical students continue to display an interest in general practice, if one may judge by the choice of careers expressed by 552 internship applicants at the University of Colorado Medical Center Hospitals for 1955 and 1956 (table 3). The 522 senior students were drawn from 65 medical schools in the United States and Canada, and represented about 4% of all the graduates of American medical schools for these two years. The students who expressed a definite or probable preference for general practice greatly outnumbered those choosing any specialty. These applicants, however, may not represent a true cross section of American senior medical students, because the data may be distorted by being weighted with students preparing for general practice who apply here because of geographical characteristics of Colorado or because of the pioneering efforts of the University of Colorado in providing general practice residency training. Nevertheless, these data suggest that interest in general practice is far from dead among today's medical students.

There can be little doubt that the general practitioner is here to stay, but his role is changing and will continue to change. The prototype of the modern general practitioner is a highly educated, astute young physician, skilled in broad areas of practice, and particularly skilled in human relations, with an unusual ability to handle people. He is motivated by a sincere interest in mankind and the ailments that afflict it. Residency training of high quality is just as essential to him as it is to any specialist.

Opportunities for Residency Training

The type of residency offered the prospective general practitioner in the past usually consisted of either a patchwork of unorganized leftovers from specialty residencies or an extension of a rotating internship. Many physicians preparing for general practice therefore elected to take one or more years of residency in one or more specialties, and this plan continues to be a frequent choice even today. It leaves obvious gaps in their training, with little or no educational exposure to important areas of their future practice. Furthermore

---

From the University of Colorado School of Medicine.

Read before the Advisory Board for Medical Specialties at the 52nd Annual Congress on Medical Education and Licensure, Chicago, Feb. 12, 1956.

the first year of a specialty residency seldom provides a well-rounded experience or a basic background even for that specialty, and it is only natural for a specialty service to give preference in appointments and assignments to those residents indicating their intention of completing the entire program

The development of the general practice residency may be traced in the Annual Reports on Internships and Residencies by the Council on Medical Education and Hospitals of the American Medical Association A 'Mixed Residency' was listed in the years prior to 1948 This title was changed to "General Residency' in the 1948 and 1949 reports These categories carried the following footnote "Mixed residencies represent general hospital experience of at least one-year duration following an approved internship All hospitals approved for intern training are also certified for general or mixed residencies It appears that these training programs were without definite educational standards and were essentially nothing more than a continuation of the internship for an additional year

The 1950 annual report listed 'General Practice Residencies' for the first time, and hospitals desiring programs under this category had to meet certain requirements The report listed 32 programs, which provided 92 positions, accounting for less than 0 5% of the 19,364 approved residency positions of all types These numbers have slowly increased, and in 1955 there were 155 approved programs, offering 614 positions, still only a little more than 2% of the now 25,486 approved residency positions of all types The growth of residency positions in the United States over the past 20 years is shown in the figure which clearly demonstrates the lag in growth and the obvious inadequacy in the number of general practice residencies available

Table 1—*Physicians in Active Private Practice in the United States April, 1950—Distribution by Size of Community**

	General Practitioners	Part Time Specialists	Full Time Specialist	Total
Cities with population of 10 000 or less (12 529 communities)				
No of physicians in active private practice	26 761	6 155	4 245	37 161

* Data from Dickinson [1]

While the number of general practice residencies is clearly inadequate, the educational standards of those which do exist require critical reexamination, for there are many indications that all is not well Perhaps the most serious indictment is that great numbers of prospective general practitioners continue to seek fragments of specialty residencies in preference to the general practice residency opportunities now available This is attested to by the fact that only 66% of the meager number of approved general practice residency positions were filled for the year 1954-1955,[2] and many of those which were filled were occupied by foreign physicians In July, 1953, 38% of all general practice residents serving in approved programs were aliens This compares with 21% in approved residencies of all types, and is surpassed only by the 41% in pulmonary disease residencies [3] In the year 1955-1956, 4,174 foreign physicians were reported to be in residency training in United States hospitals in 35 different specialties The number in general medicine was surpassed only by those in general surgery [4]

* Data from Dickinson [1]

In some instances general practice residencies are offered by hospitals which are having difficulty securing interns, and one cannot help wondering whether the primary motivation may be to provide intern services The stipends paid general practice residents tend to be higher than those paid most specialty residents A median stipend of $250 per month is offered by the 155 approved general practice residencies listed in the 1955 report of the Council on Medical Education and Hospitals, and almost one-third of these hospitals offer stipends ranging from $300 to as high as $500 per month As in the case of internships, one may justly suspect that excessively high stipends may indicate a greater interest in the service aspects of the internship or residency than in the education aspects

From these considerations, one may be quite certain that the number of general practice residencies is far too small, and one may well entertain concern that many are deficient in planned educational experience The opportunities for developing really superior training programs for general practice are unlimited

Role of Surgery in General Practice

An intelligent definition of the requisites of a general practice residency can not be formulated until one has a clear picture of the role of the general practitioner On this, there is no meeting of the minds, and there are almost as many opinions as there are specialists Judging by staff regulations in a growing list of hospitals, each specialty appears reluctant to assign significant segments of its "empire' to the realm of general practice, but willingly relinquishes its unwanted chores At the same time, specialists seem to have no hesitancy in appropriating functions of the general practitioner It has been said in jest that a surgeon is a general practitioner who does not deliver babies and an internist is a general practitioner without benefit of surgical fees

There are many areas of controversy over the role of the general practitioner, but the hub of the conflict revolves around the practice of surgery How much surgery, if any, should be performed by the general practitioner? And therefore, how much surgery, if any, should be taught to the general practice resident? If four or five years of residency are required to adequately train a general surgeon, then how can we hope to cram enough of the essentials of surgery into a three-month, or a six-month, or even a full-year surgical assignment? Is it not better to teach the general practice resident no surgery at all rather than a modicum, because a little knowledge may be a dangerous thing? Is there not a real danger that a brief assignment on a surgical service may serve only to give the resident an inflated sense of self-confidence and leave him without a proper recognition of his own limitations?

TABLE 3.—*Choice of Fields of Practice by Internship Applicants at University of Colorado Medical Center Hospitals for Two Years Beginning July 1, 1955, and 1956**

Field	Definite Choice (295 [54%])		Possible or Probable Choice (188 [34%])	
	No	%	No	%

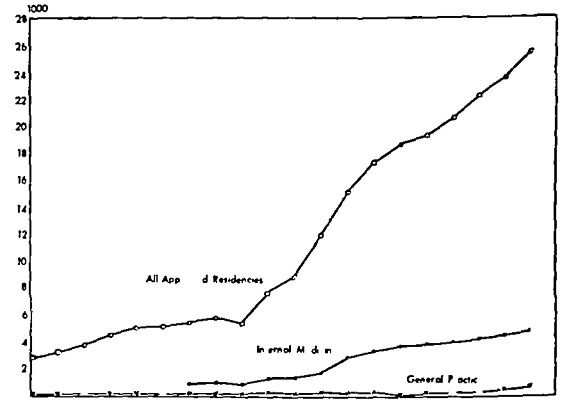
Totals	298	100	341	100

* 552 applicants from 65 medical schools in U S and Canada 66 (12%) expressed no choice

Conversely, suppose you or I should become the victim of an auto accident in an isolated area, a hundred miles or more from the nearest board-qualified surgeon Would we not be most grateful if the general practitioner who must patch us up has had even a brief period of residency training in surgery? It is not within the scope of this paper to debate the merits or the evils of the practice of surgery by general practitioners But, whether we like it or not, in many areas of this country a large portion of general surgery continues to be performed by general practitioners, and in some states their work accounts for as much as 70% of all the general surgery General practitioners will continue to perform operations even without the benefit of residency training albeit probably less ably It has long been a common practice, and one which still persists for the general practitioner to obtain his surgical education through on-the-job training, assisting older general practitioners at operations and receiving more or less supervision from them on their own cases While at times this may be a satisfactory experience, I fear that, on the average, the method tends to perpetuate all the faulty surgical techniques and obsolete operations from one generation of general practitioners to another The method is especially deficient in instilling into the neophyte a sound knowledge of the proper indications for surgery or, more correctly, a knowledge of when not to operate

Completely satisfactory answers to these questions are not at hand It is clear, however, that the objective of a general practice residency should not be to train young physicians to compete for major surgical privileges in areas where fully trained surgeons are readily available, nor should it ever be used as a training short cut for a frustrated would-be surgeon These concepts are only common sense, and are in the best interest of the patient's welfare But is it not equally clear, also in the interest of patient welfare, that surgery must be taught to those general practice residents who will be required, in an isolated area, to perform operations in cases of trauma or in emergencies? In my opinion, the general practice resident preparing for rural practice should be taught the principles of surgical diagnosis, the indications for operative and nonoperative treatment, and the essentials of preoperative preparation and postoperative care He should also be taught basic surgical techniques, especially those applicable to emergency operations and those in cases of trauma, and be given adequate opportunity to practice these under supervision Such knowledge surely will not lead him into a false sense of self-confidence or promote blindness to his surgical limitations, but quite the contrary With ever-improving transportation, and with an ever-increasing supply of fully trained young surgeons becoming available for smaller communities perhaps the present situation may be looked upon as a temporary compromise I have been impressed by the increasing number of general practice residents who do not intend to practice major surgery and who do not desire assignments on the surgical services



Growth of number of residency positions in approved programs in United States

University of Colorado General Practice Residency

Original Program.—When the general practice residency was organized at the University of Colorado School of Medicine in 1948, it was the aim of the faculty to make it equivalent in educational content and training opportunities to a specialty residency in a university teaching hospital The general practice resident, along with all others, was required to register each quarter in the clinical division of the graduate school of the University of Colorado (This requirement has now been made optional for all residents of the medical center) While accumulated experience has changed some of the concepts of the requirements, the primary objective has been maintained Originally, the faculty was of the opinion that a three-year residency was necessary to adequately prepare a young physician to enter general practice While this may still be true, it was learned that it is not realistic, for only 4 of 88 residents completed the full three years A regular rotation of services was designed to give broad experience in the major fields of clinical practice, but this was never fully implemented because the program departed from a rigid schedule and became highly flexible as to both duration and content Schedules were individually tailored in an attempt to meet the needs and desires of each resident Superficially this seemed to be an ideal plan, and it is in agreement with the recommendations of “The Essentials of a General Practice Residency’’ But serious disadvantages soon became evident This plan assumed unjustifiably that a young and inexperienced physician was in a position to know precisely what he required for practice The fallacy was disclosed by the frequency with which residents asked to change their schedules All too often, a resident would end up with an unbalanced program that was notably deficient in training for important segments of his future practice Because only a limited number of positions were available on several key services which were in greatest demand, favoring the needs and desires of some residents to the detriment of others could not be avoided After years of struggling with individualized programs, it seemed that one could never arrange a schedule that perfectly honored the needs of all It may be noted that approved specialty residencies do not offer such wide freedom of choice in assignments, nor is it deemed desirable

Revised Program —A comprehensive revision of the general practice residency at the University of Colorado became effective July 1, 1956 In its formulation, several concepts were believed to be important

1 The program should be one of graduate education having standards equivalent to those of a university hospital specialty residency

2 Two years is the minimal period of training in which a well-rounded and reasonably complete rotation can be accomplished through those clinical fields of greatest importance in general practice An optional third year is desirable for those wishing optimal training

3 General practice residents fall into two classes, those preparing for practice in rural or isolated communities and those preparing for a family-type practice in larger communities where adequate specialty consultation is available Two different programs to prepare for these two types of practice should satisfy the needs of the great majority of residents

4 Rather than flexible or individualized schedules, regular rotation of services should be arranged to insure a well-balanced and reasonably complete educational experience

5 Assignment to a clinical service should be for a long enough period for the resident to become adequately oriented to the field and its problems Three months is considered to be the minimal acceptable assignment, except for a limited number of subspecialty electives

The revised two-year program offers a choice of two types of training During the first year, the schedule of services is the same for all residents In addition to three-month assignments on the medical wards and on the pediatric service, there are two assignments which are especially designed for general practice residents In the general medical clinic, each resident serves for a period of three months Here he practices comprehensive medicine on his own patients and families, under the supervision of a full-time and volunteer faculty with special interest in this type of medicine The resident has an opportunity to follow his patients for prolonged periods by returning to the clinic one day or two half-days weekly during subsequent assignments While assigned to this clinic, the resident also works on the emergency room service

The other special assignment consists of three months spent in one of the affiliated small community hospitals staffed primarily by general practitioners Here the resident participates in small hospital practice away from a teaching medical center and in the kind of environment where he will eventually practice This experience provides insight into many of the problems that occur in small hospitals as well as the practical problems of medical economics and sociology Visits to practitioners offices in the community provide opportunities to observe and discuss equipment requirements, bookkeeping and record systems, and other essentials of practice

In the second year, the resident is offered a choice of either a “medical’ or a “surgical’ year In the ‘medical’ year, six months are divided between the psychosomatic medicine service and the medical outpatient clinics, including a variety of medical subspecialty clinics Combining these services seems more desirable than giving two three-month, full-time assignments, for it permits the resident to follow his patients over longer periods of time The remainder of the year is devoted to obstetrics (three months) and to electives (three months) There may be a second three months of pediatrics for those with a special interest in this field

The second-year ‘surgical program includes a three-month assignment on an active orthopedic and fracture service which affords both hospital and outpatient experience Six months are devoted to general surgery, the time being divided between the surgical service of the university medical center hospitals and an affiliated surgical service at the Bernalillo County-Indian Hospital at Albuquerque, N Mex This hospital service was selected because of an unusual wealth of clinical material and an exceptional opportunity for resident responsibility combined with adequate teaching supervision This is provided by a capable attending staff and two advanced surgical residents rotating from a Veterans Administration hospital These services emphasize experience in emergency surgery and that after trauma as well as common elective operations A three-month assignment on the obstetrics and gynecology service at the Bernalillo County-Indian Hospital completes the second year An individualized elective third year of residency is available for those desiring optimal training

Comment

Twelve statements may be made which summarize my conception of the essentials of a general practice residency

1 The general practice residency should be equivalent in educational standards and training opportunities to a specialty residency

2 The assignment of a resident to any service should be primarily for the educational value rather than for service considerations

3 Two years is the minimal time in which an adequate rotation can be accomplished through the clinical services which are of major importance in general practice

4 Assignment to a clinical service should be long enough to ensure an adequate orientation to the problems of the field Assignments should rarely be for less than three months, with the exception of a minimal number of subspecialty electives

5 The general practice resident should have opportunities for patient responsibility commensurate with his ability, and in general such responsibility should be equivalent to that of a first-year specialty resident

6 Experience in the management of ambulatory patients should be emphasized The resident should have an opportunity to develop rapport with his own patients and to follow them over a prolonged period, extending through the time he is assigned to various services Throughout the ambulatory patient experience, the resident should have easy access to an interested and competent staff for discussion, consultation, and guidance in clinical problems

7 Primary teaching responsibilities are best assumed by the specialist staff of the service to which a general practice resident is assigned It is believed that the specialist is best able to transmit an organized body of specialized knowledge and skills, but it is essential that he have a sympathetic attitude toward the general practice resident and a recognition of his special problems

8 If the staff of a hospital offering a general practice residency does not have an active organized general practice section, then a short affiliation should be arranged in a hospital which is staffed primarily by general practitioners, preferably in a small community hospital in a rural area

9 Two different programs of two years' duration should be offered to meet the needs of two classes o residents, those preparing for practice in an isolated community and those preparing for a family-type practice in larger communities where specialty consultation is available These should replace schedules which are flexible as to duration and content, and regular rotations of services should be provided which ensure a well-balanced and reasonably complete educationa experience

10 If surgical training is offered, it should occupy all or most of an entire year and should be designed to specifically prepare the resident to cope with traumatic and emergency situations Surgical diagnosis surgical principles, and minor surgery should b stressed Time spent in the operating room should b devoted to assisting with and performing common emergency and elective procedures rather than assisting with advanced, highly specialized operations

11 The general practice residency must be conducted in a sympathetic atmosphere, one which offer the resident a dignity and prestige equal to that of th specialty residents

12 Finally, the general practice residency should engender good attitudes and high ideals as well a skills, and should make the resident proud to be in hi chosen field The resident should be stimulated to become a lifetime student, so that, after 20 years of practice, he can truly say that he has had 20 years of experience, not one year s experience 20 times

Monocytic Leukemia —Two varieties of monocytic leukemia are generally recognized In one (Schilling type), the leukemic cells are believed to arise from the reticuloendothelial system, because of which the terms ‘reticulosis,’ leukemic reticuloendotheliosis, and ‘histiocytic leukemia are often applied In the other form (Naegeli type), the cells are thought to arise from primitive cells in the bone marrow (monoblasts, myeloblasts) In the Schilling type there have been difficulties in distinguishing leukemia and aleukemic neoplasias from non-neoplastic hyperplasias, in the Naegeli type, monocytic and myeloid leukemias are not always clearly distinguished from each other The clinical, hematologic, and pathologic features of these two types have been described in detail Nevertheless, there continues to be uncertainty regarding the frequency and extent of reticuloendothelian participation —M N Richter, M D, Origin of Leukemic Cells in Monocytic Leukemia, *Laboratory Investigation*, March-April, 1956

EFFECTS OF CYCLOPROPANE ANESTHESIA ON THE CIRCULATION OF HUMAN BEINGS

Murray C. Thompson, M.D., Robert T. Patrick, M.D.
and
Earl H. Wood, M.D., Ph.D., Rochester, Minn.

• *Seven patients, while under various electroencephalographic levels of cyclopropane anesthesia, were studied in relation to hemodynamics. Measurements included cardiac index, pulse rate, stroke volume, peripheral resistance of the circulatory system, and central, arterial, and venous pressures. The various levels of anesthesia caused changes in most of the measurable factors, but all alterations returned to preanesthetic levels as the anesthetic was withdrawn.*

Investigations of hemodynamics during anesthesia with cyclopropane have been carried out in man and in animals. Evidence has been presented in these publications demonstrating both increased and decreased cardiac output.[1] The study described herein was undertaken to correlate cardiac output, level of arterial blood pressure, peripheral resistance, and central venous pressure with depth and duration of anesthesia with cyclopropane in man.

Method

Seven surgical patients with no discernible cardiovascular or pulmonary disease were studied (table 1). Each patient was in the supine position throughout the period of observation. In each patient loss of blood was minimal, and in no instance was a vasopressor agent used. Respirations were assisted in all but one patient.

A needle was inserted into the radial artery and connected with a cuvette oximeter[2] and strain-gauge manometer.[3] A cardiac catheter was passed centrally through an arm vein until its tip lay in the region of the superior vena cava. This catheter was connected to a strain-gauge manometer. Another strain-gauge manometer was connected to the airway assembly. An earpiece oximeter[2b] was placed. Electrocardiographic electrodes were secured to the right and left arms and the left leg. Electroencephalographic scalp electrodes were inserted in the skin over the frontal and occipital regions. Thus, the following variables were recorded continuously: blood pressure in the radial artery, central venous pressure, pressure in the airway, oxygen saturation of arterial blood, heart rate and rhythm, and the depth of anesthesia.[4]

At predetermined periods, arterial dye-dilution curves were recorded simultaneously at the radial artery and the ear, and samples of arterial blood were withdrawn to determine the pH. The dye solution in a volume of 1 or 2 cc. was injected as rapidly as possible via the catheter into the superior vena cava. The average dose of Evans blue dye (T-1824) for each curve was 10 mg. The first dye-dilution curve was recorded while the patient was conscious and breathing pure oxygen 30 minutes after the intravenous administration of 10 mg. of morphine sulfate and 0.4 mg. of atropine sulfate. Anesthesia with cyclopropane and oxygen was then induced. The second dye-dilution curve was recorded when the patient had attained a light level of anesthesia, electroencephalographic level 2. Sufficient dimethyl tubocurarine (Metubine) iodide was given intravenously to facilitate tracheal intubation during light anesthesia. The third dye curve was recorded after intubation and during light anesthesia. Deep anesthesia, or anesthesia of electroencephalographic level 4, was induced, and a fourth dye-dilution curve was recorded. The patient was permitted to return to a light level of anesthesia, and a fifth dye curve was recorded.

TABLE 1.—*Data on Seven Patients Studied While Under Cyclopropane Anesthesia**

Case No.	Age, Yr.	Sex	Weight, Lb.	Body Surface, Sq. M.
1	49	M	159	1.86
2	43	F	140	1.64
3	48	M	185	1.98
4	53	M	173	1.85
5	40	F	152	1.71
6	53	F	132	1.65
7	[illegible]	F	195	1.90

* All patients underwent cholecystectomy.

From the arterial dye-dilution curves, cardiac output was calculated by the conventional Hamilton method.[5] Stroke volume, peripheral resistance, and central blood volume were calculated also.

Results

Cardiac Index.—The cardiac index values are shown in table 2 and figure 1. The mean cardiac index of all conscious patients breathing pure oxygen was 4.2 liters per minute per square meter of body surface, with a range of from 3.2 to 6.5 liters. The cardiac index decreased in all patients in anesthesia of electroencephalographic level 2 before intubation to a mean of 3.0 liters per minute per square meter, with a range of from 2.3 to 4.2 liters. After intubation the mean cardiac index was 3.8 liters per minute per square meter, with a range of from 2.8 to 5.2 liters. When anesthesia was deepened to electroencephalographic level 4, the cardiac index decreased in all

The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

Read before the Section on Anesthesiology at the 105th Annual Meeting of the American Medical Association, Chicago, June 14, 1956.

patients from that during intubation and in four patients from that at level 2 before intubation, the mean cardiac index at level 4 anesthesia was 2.5 liters, with a range of from 1.8 to 3.2 liters With return to anesthesia of electroencephalographic level 2, the cardiac index in all patients increased, the mean cardiac index was 3.4 *liters per minute per square meter*, with a range of from 2.1 to 5.3 liters

Pulse Rate.—The pulse rates are shown in table 2 and figure 1 The mean pulse rate of all conscious patients was 92 beats per minute, with a range of from 69 to 120 beats The heart rate of all patients but one decreased in anesthesia of electroencephalographic level 2 before intubation to a mean pulse rate of 74 beats per minute, with a range of from 51 to 102 beats After intubation, the mean pulse rate was 87, with a range of from 60 to 100 beats A decrease in pulse rate was found in all patients in anesthesia of electroencephalographic level 4, the mean pulse rate was 66, with a range of from 48 to 82 beats An increase in pulse rate was found on return to electrocardiographic level 2, the mean pulse rate was 80, with a range of from 60 to 102 beats

Stroke Volume.—The stroke volumes are shown in table 2 and figure 1 The mean stroke volume of all conscious patients was 43 cc per heart beat per square meter of body surface, with a range of from 36 to 50 cc The mean stroke volume in anesthesia of electroencephalographic level 2 before intubation was 41 cc per beat per square meter, with a range of from 35 to 50 cc The stroke volume in one patient increased by 13 cc after intubation When anesthesia was deepened to electroencephalographic level 4, the stroke volume decreased in all but two patients in whom no changes were noted The mean stroke volume was 37 cc per beat per square meter, with a range of from 30 to 40 cc With return to anesthesia of electroencephalographic level 2, stroke volume increased in all but one patient in whom it decreased by 2 cc The *mean stroke volume was 42 cc per beat per square meter*, with a range of from 31 to 55 cc

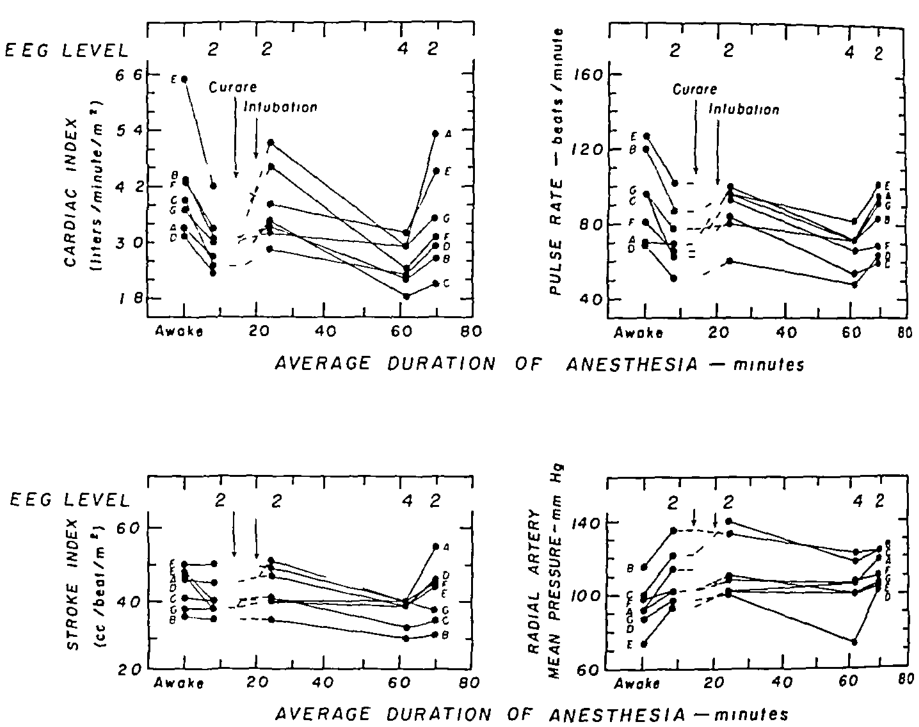

Fig 1.—Graphs showing changes in cardiac index, pulse rate, stroke volume, and mean pressure in radial artery during cyclopropane anesthesia Letters A to G represent cases 1 to 7 as listed in tables Solid dots represent average time at which observations were made and values for individual patients are connected Broken line represents average time taken to administer curare and intubate patient Cardiac index and pulse rate parallel each other closely with significant decrease in light anesthesia (electroencephalographic level 2) and further decrease in deep anesthesia (electroencephalographic level 4) and return toward values when awake on lightening level of anesthesia

Peripheral Arterial Blood Pressure.—The mean pressure in the radial artery of all conscious patients was 94 mm Hg Before intubation in all patients under anesthesia of electroencephalographic level 2, it increased to 109 mm Hg, with a range of from 94 to 135 mm Hg (table 3, fig 1) After intubation, the

* After preceding observation

Central Venous Pressure—The mean central venous pressure of all conscious patients was 7 mm Hg, with a range of from 3 to 12 mm Hg (table 4) A significant increase in central venous pressure was found while the patient was in a light level of anesthesia, the mean pressure was 10 mm Hg, with a range of from 5 to 13 mm Hg In deep anesthesia no significant increase was evident, the mean pressure was 9 mm Hg, with a range of from 4 to 15 mm Hg On return to a light level of anesthesia a significant decrease in central venous pressure was evident, the mean pressure was 7 mm Hg, with a range of from 4 to 11 mm Hg

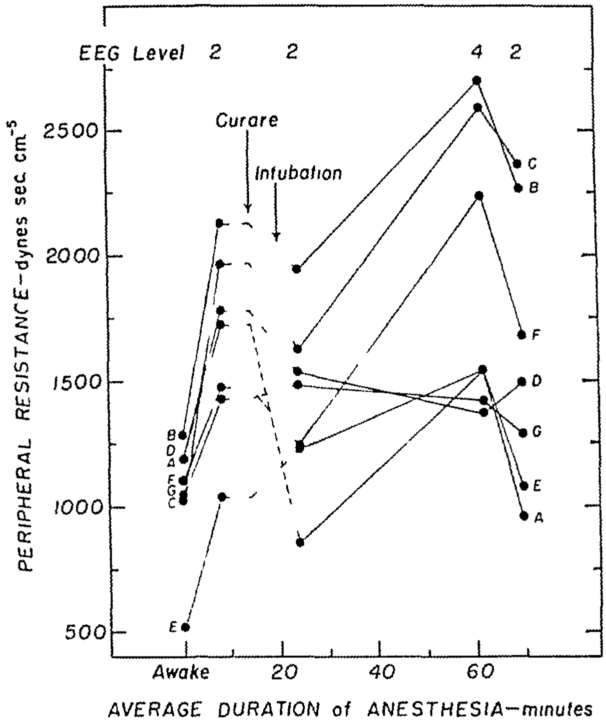

Fig 2 —Graph showing changes in peripheral resistance during cyclopropane anesthesia Peripheral resistance increased significantly at all levels of anesthesia Increase in peripheral resistance varies directly with depth of anesthesia Letters A to G represent cases 1 to 7 as listed in tables

pH of Arterial Blood—The mean pH of arterial blood was 7 34, with a range of from 7 13 to 7 50 In only one patient was a marked change in pH noted, and this was noted during deep anesthesia when the pH fell to 7 13 The lowest pH noted among all other patients was 7 23

Electrocardiographic Changes—Electrocardiographic changes were observed in one patient This change consisted of a bigeminal type of pulse, observed during a deep level of anesthesia and disappearing on lightening of the level of anesthesia

Arterial Oxygen Saturation—All patients during this study were receiving 50% oxygen or more, and the arterial oxygen saturation ranged from 93 to 100% There was no correlation between changes in arterial oxygen saturation and depth of anesthesia

Central Blood Volume—The average central blood volume before the induction of anesthesia was 1 5 liters per minute, with a range of from 0 92 to 2 1 liters There were no significant systematic changes in central blood volume with varying depths of anesthesia (table 5) Significant increases in mean circulation time of the dye [1e] were obtained during a light level of anesthesia, with no significant change in mean circulation time in deep anesthesia On emergence from deep anesthesia a significant decrease was noted Thus the mean circulation time reflected changes in cardiac output rather than in central blood volume

Comment

Under the conditions of these observations a decrease in cardiac index was uniformly seen with the onset of light anesthesia with cyclopropane As anesthesia deepened to level 4, the cardiac index decreased further in four of the seven patients With return of anesthesia to light levels, values for cardiac index increased rapidly toward those initially observed in all patients Therefore the decrease in cardiac index appears to be directly related to depth of anesthesia During light anesthesia the decrease in cardiac index reflects primarily a decrease in pulse rate rather than in stroke volume whereas the decrease in cardiac index in deep anesthesia reflects decreases in both pulse rate and stroke volume The decrease in pulse rate may be due to a reflex response of the heart to increased arterial pressure or may represent direct depression of that part of the heart initiating the cardiac impulse It is possible that cyclopropane directly depresses the myocardium, thus accounting for the decrease in stroke volume The observed increases in central venous pressure would be compatible with this interpretation

Since respirations were assisted in these patients, it is possible that the decrease in cardiac index was in part due to increased pressure in the airway However, it is our impression that the mean airway pressure was not greater during deep levels than during light levels of anesthesia and that the variations in cardiac index under these conditions are attributable to the cyclopropane

Peripheral resistance increased with light anesthesia and increased further during deep anesthesia However, as anesthesia was lightened again, peripheral resistance decreased rapidly Therefore, the change in peripheral resistance was related directly to depth of anesthesia It is interesting to note that the decreased cardiac output and pulse rate and the increase in mean arterial blood pressure and peripheral resistance found in this study paralleled those observations found in patients after being given infusions of levarterenol (*l*-norepinephrine) bitartrate [6] There is some evidence that the concentration of epinephrine-like substances in the blood is increased during cyclopropane anesthesia [7] The mean peripheral arterial blood pressure level was increased at all levels of anesthesia over the preanesthesia level, and, since all levels of anesthesia were accompanied by a decrease in cardiac output, it would appear that the increase in peripheral arterial blood pressure was a result of increased peripheral resistance

All hemodynamic variables returned rapidly toward preanesthetic values on lightening of the level of anesthesia This is compatible with rapid elimination of cyclopropane from the patient and offers an explanation for the value obtained after intubation During the period of intubation when the patient was breathing air, cyclopropane was rapidly lost by exhalation and anesthesia became lighter Anesthesia of electroencephalographic level 2 was induced again in each patient The resulting changes in the hemodynamic variables were probably due to failure of the patient to reach an anesthetic equilibrium at this level before observations were made

Of interest in this study was the cardiac arrhythmia that occurred in one patient (case 1) The arrhythmia occurred during deep anesthesia only and was co existent with a low pH of arterial blood and depressed respirations This was the only patient in the series whose respirations were unassisted

Summary

Hemodynamic variables were studied while seven surgical patients were in different electroencephalographic levels of cyclopropane anesthesia Cardiac index and pulse rate decreased with increasing depth of anesthesia The stroke volume showed no significant change during light anesthesia, during deep anesthesia a significant decrease was noted Peripheral resistance increased with increasing depth of anesthesia An increase in arterial blood pressure over preanesthetic levels was observed at all levels of anesthesia There was no consistent change in calculated central blood volume, but a moderate increase in central venous pressure occurred during anesthesia The hemodynamic alterations during cyclopropane anesthesia rapidly returned toward preanesthetic values on lightening of the level of anesthesia

Hormone-Dependent Cancers—Reviewing our present knowledge of hormones in relation to cancer, we can say that certain cancers of the breast and of the prostate are hormone-dependent, in such cases, if the stimulating hormone is removed from the body by operation, or neutralized by giving an antagonistic hormone, the tumour regresses Other tumours of these organs are hormone-independent Possibly some tumours which first show a regression following removal of the hormonal stimulus but which later relapse, may have changed their character from a hormone-dependent tumour to a hormone-independent tumour, but we cannot be certain of this as yet, in some relapsing cases production of the stimulating hormone elsewhere in the body, as in the glandular "rests may bring about a reactivation of the tumour Mammary cancers may be classified into œstrogen-dependent and non-œstrogen dependent tumours If the ovaries produce almost all the circulating œstrogen in the body in some premenopausal women and the adrenals either none at all or an amount below the threshold of tumour stimulation, then there may be a regression following oophorectomy, the subsequent relapse may be due to a gradual increase in the output of œstrogen from the adrenal In other premenopausal women a regression probably only follows the removal of both the ovaries and the adrenals Within these limitations therefore we can use the terms ovary-dependent and adrenal-dependent tumours In the postmenopausal group, when the ovaries are partly atrophied, the adrenals produce most of the œstrogen, hence the removal of the adrenals as well as the ovaries is necessary to bring about a regression The evidence suggests that there is also a growth-hormone dependent tumour, so that hypophysectomy may cause a regression in some cases which have not been influenced by oophorectomy and/or adrenalectomy Many prostatic cancers are androgen-dependent and testis-dependent, dependence upon the adrenal appears to be much less common than in mammary cancers—L N Pyrah, Hormones in the Treatment of Cancer of the Breast and Prostate, *The British Journal of Surgery*, July, 1956

CYSTINOSIS IN AN ADULT

David G Cogan, M D Toichiro Kuwabara, M D, Jin Kinoshita, Ph D, Linus Sheehan, M D
and
Lorenzo Merola, B S, Boston

• *In contrast to the disease in children, which is usually fatal, cystinosis (deposits of cystine crystals in tissues of the body) in the two reported instances occurring in adults was a relatively benign condition This condition, sometimes called Lignac Fanconi syndrome, should not be confused with benign cystinuria of adults, in which the cystine level in the urine is elevated but there are no crystals in tissues In the case reported, cystine crystals were discovered in the cornea and conjunctiva during a routine examination*

Cystinosis, or the Lignac-Fanconi syndrome, is a well-established entity,[1] occurring in infants and children, wherein crystals of cystine are deposited in many tissues of the body, including the cornea and conjunctiva Here the crystals can be seen, by slit-lamp examination, to have a characteristic appearance and distribution that can be differentiated readily from any other condition Patients with cystinosis usually fail to grow properly (dwarfism) and have renal tubular disease with consequent glycosuria, aminoaciduria, and hypokalemia Rarely have such patients survived the first decade of life

We have had occasion to study a normal adult who had crystalline deposits in his corneas and conjunctivas identical to those that have been described in children and infants with cystinosis The crystals had the same distribution clinically and histologically and they gave the same results histochemically and chromatographically as we and others have previously found with crystals from the conjunctivas of patients with cystinosis We are aware of only one possibly similar case of cystinosis in an otherwise normal adult, reported by Burki and Rohner[2] This was in a 50-year-old woman who was found to have crystals in the cornea that were clinically similar to those found in infants with cystinosis No crystals were seen in the conjunctiva, and no biopsy was done Systemic investigation showed only a questionably significant aminoaciduria

The significance of these two cases lies in the inference that cystinosis in the adult is a benign condition, in contrast to the disease in children, which is almost universally fatal

Report of a Case

The patient was a 23-year-old university student who was incidentally discovered to have crystals in his cornea and conjunctiva during a routine examination for refraction The only symptoms referable to his eyes were those attributable to a low degree of myopia Excepting for one occasion when at the age of 9 years he was told that urinalysis indicated that he had diabetes, he had had no significant medical abnormality and he had developed normally The results of several subsequent urine tests and one blood sugar determination were said to have been normal

The patient was 6 ft (183 cm) in height, weighed 180 lb (81 6 kg), and showed normal osseous and muscular development Nothing of significance was found on physical examination except mild acne of the face and back The blood pressure was 152/84 mm Hg There were no tophi and there was no limitation of joint movement and no enlargement of the liver

The only significant abnormality found was in the eyes and here the changes could be seen definitely only on slit-lamp examination The faintest possible haze of the cornea could be seen by the naked eyes with strong focal illumination, and nothing abnormal could be seen by ophthalmoscopy The corrected visual acuity was 20/15 in each eye When viewed by slit lamp biomicroscopy, however, the corneas were seen to be uniformly studded with a myriad of highly reflectile particles situated in the anterior half of the stroma centrally but extending throughout the entire thickness of the stroma peripherally In this latter region a lamina of the particles was situated just in front of the posterior surface extending several millimeters toward the pupillary area so that the particles had an hourglass distribution in the periphery of the cornea The particles extended across the limbus without any line of demarcation

The individual particles appeared with the high magnification (×20) to consist of conglomerates of highly reflectile polychromatic needles arranged in a random fashion They did not fluoresce with ultraviolet light An attempt was made to photograph them with the Donaldson camera (*fig 1*)

The conjunctivas also showed numerous abnormal deposits scattered throughout the superficial stroma In apparent contrast to those in the cornea, these particles appeared chalk-white and nonreflectile They were more obviously clumped and not as uniformly distributed as in the corneal stroma They did not appear to be oriented about the blood vessels or any other recognizable structure of the conjunctiva Because of the white background of the sclera, they were less conspicuous than those of the cornea and could not be photographed

A preliminary urinalysis done prior to the patient s hospitalization showed a trace of reducing substance in the urine when it was tested with Fehling s solution, but subsequent 24-hour specimens showed no reducing substances The alpha amino nitrogen excretion in a 24-hour urine sample was 89 mg per liter with a total nitrogen level of 16 2 Gm per liter, thus showing that 0 55% of the nitrogen in the urine was directly attributable to amino acids The uric acid level was 81 mg per 100 cc Blood studies, interpreted as normal, gave the following results the level of uric acid was 5 3 mg per 100 cc of carbon dioxide, 32 mEq, of sodium 137 mEq, of potassium 4 4 mEq, and of chlorides 100 mEq per liter, the pH was 7 48

An elliptical piece of conjunctiva measuring 4 by 7 mm was removed from the temporal portion of one eye for chromatographic and histological study Sections were cut with the specimen in the fresh-frozen state and after it had been fixed with alcohol After approximately 30 sections had been cut the remaining tissue was placed in 5 ml of 4% formaldehyde solution for 18 to 20 hours This dissolved out the crystals (as shown by section of the remaining tissue), and the formaldehyde solution was filtered and brought to dryness in a vacuum The residue was repeatedly dissolved in 1 *N* hydrochloric acid and dried to insure total removal of the formaldehyde The residue was then dissolved in 5 ml of water and dried to remove the hydrochloric acid Finally, the dried residue was dissolved in 0 1 ml of 0 1

From the Howe Laboratory of Ophthalmology Harvard Medical School and the Massachusetts Eye and Ear Infirmary

N hydrochloric acid and the solution concentrated to 10 to 20 microliters The concentrate was spotted on Whatman no 1 filter paper for chromatographic separation and identification

Formaldehyde extracts were prepared in this way on two separate pieces of conjunctiva and chromatographed in two dimensions, with use of butanol acetic acid water (4 1 5) for one dimension and water-saturated phenol containing a 0 1% cyanide solution in the chamber for the second dimension The chromatogram was developed by ascending technique, with 21 hours in butanol acetic acid water and 20 hours in water-saturated phenol The papers were then dried and sprayed with a 2% alcoholic solution of ninhydrin for location of position of the amino acids

Solutions of 22 known amino acids were run in the same solvent systems for the same length of time for reference, but only those for which the results corresponded to the results with the spots obtained from the biopsy specimen will be mentioned Extraction and chromatography were done similarly on conjunctival biopsies obtained from two normal persons The specimen obtained from the patient here described showed spots corresponding to aminoacetic acid (glycine), tyrosine serine, oxidized glutathione cystine, alanine and leucine, while the two control specimens showed cystine, serine, leucine and alanine Although the control specimens were of the same approximate size as the test specimen the chromatographic spots were weaker for all the amino acids by a factor of approximately 3 These results were interpreted as indicating that the patient in question did show an abnormal amount of cystine in the conjunctiva as well as an excess of several other amino acids Chromatography has previously been employed several times for the identification of the conjunctional crystals in infantile cystinosis [3]

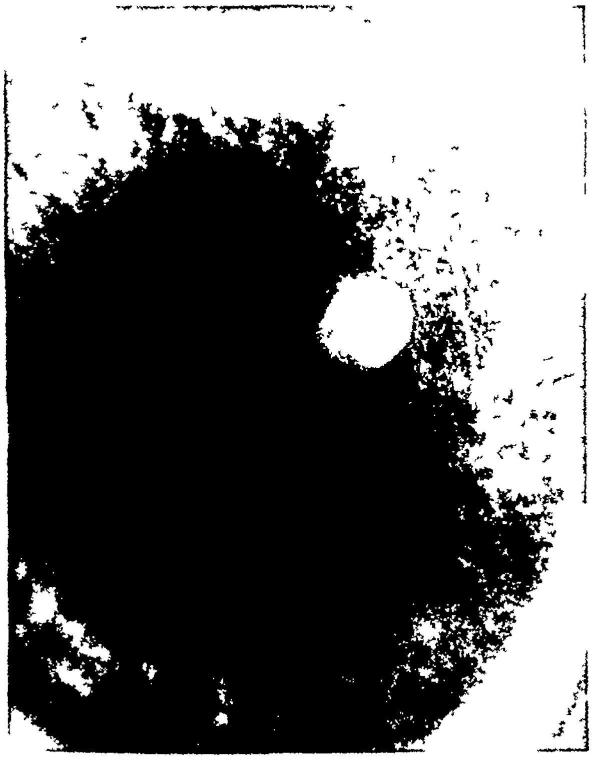

Fig 1 —Photograph of eye Highly reflectile particles can be seen about image of light reflected from cornea Actually crystals were uniformly distributed over entire anterior portion of cornea

Sections of the fresh-frozen and alcohol-fixed tissue showed abundant crystals in the region of the epithelial stromal junction, without any reaction on the part of the tissue (fig 2) The crystals were predominantly rectangles of various sizes, but all were less than 10μ, with occasional squares and hexagons Many were vividly birefringent (fig 3) The crystals appeared to be free in the tissue and were often present as clumped masses such as had been seen clinically None were definitely intracellular

The preponderance of the crystals in the epithelial-stromal area was a conspicuous feature Some of the crystals appeared to be within the deep epithelial layers and some in the most superficial stroma, but none were more than 0 5 mm from the junction Many clumps seemed to be aggregates about the rete pegs There were no concentrations in the walls of blood vessels such as we have observed in a case of infantile cystinosis [3c] The crystals did not take the eosin or hematoxylin stains, but, as previously found in the case of infantile cystinosis,[3c] they were outlined by the silver of the von Kossa stain and their visibility was thereby enhanced

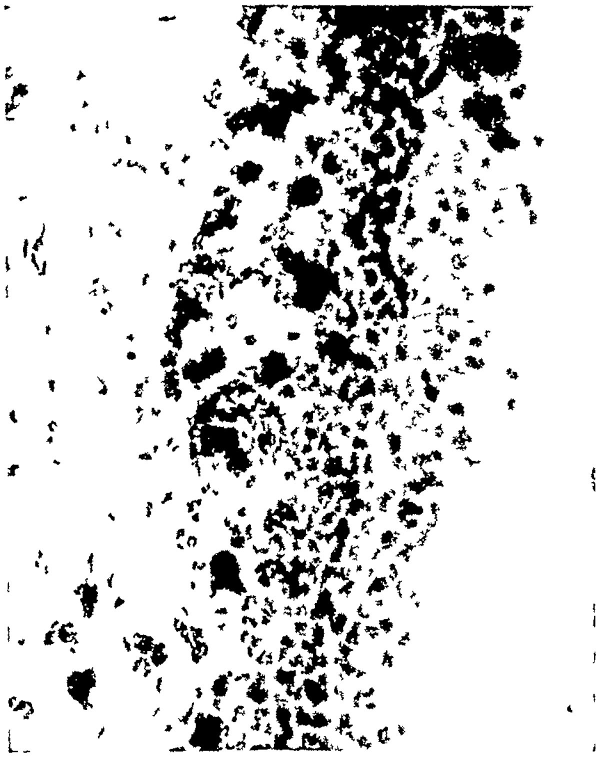

Fig 2 —Biopsy specimen of conjunctiva stained according to the von Kossa technique Crystals blackened by reduced silver can be seen predominantly situated at epithelial-stromal junction

To determine whether the crystalline deposits in the present case were identical with those in classic cystinosis of infancy, a series of sections from the present patient and from a patient with a proved case of cystinosis [3c] were immersed in solutions of different pH for various lengths of time In all instances it was found that the crystals were readily soluble in solutions of sodium hydroxide having a pH of 9 or more and slowly soluble in the pH range of 6 to 9 In acid ranges (hydrochloric acid) the crystals were more slowly soluble Known cystine crystals embedded in gelatin and treated in the same way behaved similarly The crystals in the tissue of the present patient were insoluble in ether, acetone, and chloroform and only slightly soluble in methyl alcohol and ethyl alcohol

Finally, the specificity of the crystals as cystine was established by determining their relative insolubility in a cystine-saturated solution Sections from the present patient and from a patient with known cystinosis were immersed in phosphate buffers adjusted to pH 3 8 Whereas the crystals began to disappear in about 15 minutes in solutions that had not had cystine added, they showed no change in 24 hours time in solutions that were saturated with cystine This procedure, suggested to us by Dr Morton Grant, does not appear to have been employed previously in identification of crystals in cystinosis, but it is a simple and seemingly reliable test of considerable specificity

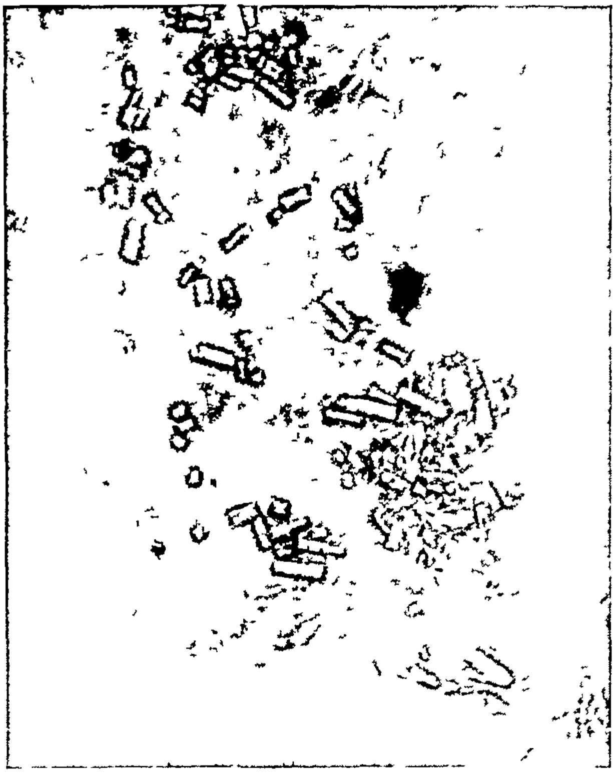

Fig 3 —Photograph of crystals in tissue taken through crossed polaroids

Comment

There can be little doubt of the identity of the ocular findings in this case and in cases of juvenile cystinosis The clinical and histological findings are identical, and the chromatographic findings and results of solubility studies are consistent with such an identification It was not possible in our case, nor in the one probably similar case previously reported, to obtain material from tissue other than the eye, but it would seem most unlikely that this deposition of crystals was limited to the cornea and to the conjunctiva It is also not possible to state how long the crystals had been present in our patient Thus we cannot state that the present case arose *de novo* in the adult What is important is that this case and the one previously reported by Burki and Rohner[2] show that, in the adult, cystine crystals may be deposited in tissues abundantly without necessarily involving a grave prognosis such as is the case in infantile cystinosis

The present case is, of course, not to be confused with the so-called benign cystinuria of adults This latter process, which appears to be due to lowered renal threshold, differs in that the cystine level in the urine is elevated but there are no crystals in tissues

The deposition of crystals in cystinosis is believed to be associated with the relative insolubility of cystine in body fluids In our patient, the striking predilection of the deposits for the subepithelial zone of the cornea (and to a lesser extent for the subendothelial region of the cornea) and for the epithelial-stromal boundary of the conjunctiva suggests that the epithelium, notoriously high in sulfhydryls, favors the local precipitation of cystine or accumulation of excess cystine

Summary

A case has been discovered of what is believed to be cystinosis in an otherwise healthy adult This is the second case of its kind in the literature and the first to have been studied histochemically and chromatographically Cystine crystals were found abundantly in the cornea and conjunctiva Although the ocular features were identical, clinically and pathologically, with those often observed in cystinosis of infants and children, the clinical course of the disease is entirely different Whereas its pediatric counterpart is accompanied by dwarfism, renal tubular insufficiency, and usually death within the first decade, the disease in the adult is entirely benign

Addendum

Since the foregoing report was submitted, Mr Jeremiah Silbert of this laboratory has succeeded in dissecting out a small quantity of the individual crystals by means of micromanipulation These crystals were subjected to chromatographic analysis (butanol acetic acid water) and found to have the same approximate Rf value as a control sample of cystine, and these values coincide most nearly with those for the cystine extracted from the conjunctiva, as described in the paper

ETIOLOGICAL ROLE OF SODIUM CHLORIDE INTAKE IN ESSENTIAL HYPERTENSION IN HUMANS

Lewis K Dahl, M D
and
Robert A Love, M D , Upton, N Y

• The possibility that a high dietary intake of sodium chloride might predispose an individual to hypertension was investigated by classifying 1,346 adults according to their blood pressure and again according to their habitual consumption of table salt The 105 persons classified as hypertensive were found not to be randomly distributed, there were 61 among the 581 persons with high salt intake, 43 among the 630 with average salt intake, and 1 among the 135 with low salt intake The departure from randomness of distribution was not explainable as an accident of sampling, and the association between salt intake and hypertension was accepted as significant Further classification of the subjects as thin, average, overweight, and fat showed that obesity further increased the probability of hypertension in people on high salt intake

In 1954 we presented evidence that was interpreted to indicate a relationship between the level of sodium intake and human essential hypertension [1] The original series of observations on 547 subjects has now been extended to include a total of 1,346 adults The earlier findings have been confirmed the data are highly suggestive of a correlation between salt (i e , sodium chloride) intake and the incidence of hypertension

The original paper [1b] may be consulted for details of the rationale The possible role of sodium in the etiology of essential hypertension in humans was suggested by (1) the need for sodium in the production of certain forms of experimental hypertension [2], (2) the virtual absence of hypertension among primitive races, all of whom appear to have a low-sodium diet [1b], and (3) the amelioration of hypertension in some persons by restriction of sodium [3] Given these three observations, the following question was suggested Did individuals who had an apparently higher salt intake have significantly more hypertension than those with a lower salt intake? If the answer were that high salt intakes were indeed associated more frequently with hypertension, a cause effect relationship would certainly be implicated, although not necessarily established While the effects of sodium and chloride could not be separated here, all experimental and clinical evidence indicated that it was the sodium, not the chloride, ion that was important For this discussion, therefore, the terms sodium chloride and salt may be interpreted to refer only to sodium

Material and Method

Early in 1953 the present study was begun on every member of the Brookhaven Laboratory staff who reported for annual physical examination to one of us (R A L) Both scientific and nonscientific personnel were included, and no selection by the physician occurred However, the following selective processes were known to be in operation 1 Pre-employment physical examinations would tend to eliminate individuals with serious diseases of any sort 2 Because of the laboratory's young age (about 10 years) and the character of the research (the study of the atomic nucleus and isotopes), the mean age of the scientists as well as their associates probably would be lower than the national average 3 The employment policies at the laboratory limited the age range to from 18 to 65 4 Females had the frequently exercised prerogative of being examined by a woman physician, so that the total sample had a 5 1 ratio of males to females

In our society it seemed likely that the major source of variation in salt intake might derive from the addition of salt at the table by the individual concerned Of perhaps equal importance, however, was the fact that this addition of salt could be qualitatively analyzed over a lifetime With this rationale in mind, each person was questioned as to his salt intake and classified into one of three groups, as follows 1 Low intake—this individual denied adding, or ever having added, salt to his food at the table (the present widespread use of low-sodium diets made it imperative to specify whether the separation from salt shakers had been recent or lifelong) 2 Average intake—this individual added salt to his food, if after tasting, it was insufficiently salty for his palate 3 High intake—this person routinely added salt to foods customarily salted before tasting them An individual who would have been classified as a member of the high or average groups by past habits, but who had changed to average or low intake for any reason, was classified as a member of the group with the greater intake to which he had belonged formerly

As mentioned earlier,[1b] certain defects in this type of classification were obvious 1 It lacked precision in estimating the intake 2 No allowance was made for variation in the salt content of foods prior to their arrival at the table due to natural variations in content as well as those diversities due to preparation, preservation, and cooking 3 No provision was made for differences in perception of saltiness among individuals or even possibly in the same individual at different times Despite these known limitations, it was believed that with sufficient members in the series some or all of these variables might be canceled out and the conceptual implication of a low versus a high salt intake might be tested

---

From the Medical Department, Brookhaven National Laboratory

At the time of the physical examination, record was made of the subject's age, sex, blood pressure, race, and nutritional state. The number of non-Caucasians proved to be so small that race has been disregarded in the calculations. Estimates of nutritional state were based upon the undressed appearance, from which each patient was classified as thin, normal, overweight, or fat. Although this classification was not exact, there appeared to be no need for more detailed anthropometric classification. The blood pressure was measured with a mercury sphygmomanometer while the patient sat quietly in the upright position with the arm resting easily on the examiner's table. Systolic and diastolic blood pressure levels were assumed to be represented by the first and fourth auscultatory phases, as recommended by a committee of the American Heart Association.[4] Hypertension was defined as a level of at least 140 mm. Hg systolic in combination with a pressure of at least 90 mm. Hg diastolic. If the blood pressure was not in this (defined) hypertensive range at the time of the examination but previous incontestable records of such elevation were available, this fact was noted and such individuals were classified as having hypertension. Although not all persons with transient elevations of blood pressure will develop sustained hypertension, available data suggest that among such individuals the disease occurs at least two or three times more often than in persons without such transient elevations.[5] It might be of added significance if even these persons with possible hypertension were found to be absent in the low-intake group.

TABLE 1.—*Uncorrected Data on Salt Intake and Incidence of Hypertension in Humans**

Sodium Chloride Intake	Total Subjects No.	Total Subjects % of Total	Subjects with Hypertension No.	Subjects with Hypertension % of Intake Group
Low	135	10.0	1	0.7
Average	630	46.8	43	6.8
High	581	43.2	61	10.5
Total	1,346	100.0	105	7.8

* The distribution of subjects with hypertension was significantly different among the three groups as tested by the chi square distribution with $\chi^2 = 16.1$ and $p<0.001$.

Sodium Chloride Intake	Age, Yr.	Males No.	Males % of Intake Group	Females No.	Females % of Intake Group
Low	35.2(±9.2)	101	74.8	34	25.2
Average	34.7(±10.3)	522	82.9	108	17.1
High	34.4(±10.0)	501	86.2	80	13.8
Total	34.6(±10.0)	1,124	83.5	222	16.5

* Sex distribution significantly different among the three groups ($p<0.01$).

Observations

The uncorrected data on 1,346 consecutive patients are shown in table 1. (Data on three subjects were excluded as of no consequence in the present study.[1b]) Very briefly, among the 135, 630, and 581 members of the low, average, and high sodium chloride intake groups, there were 1, 43, and 61 persons with hypertension respectively. The group with average salt intake had an incidence of hypertension that did not differ significantly from that predicted by random distribution and therefore is irrelevant to the development of the thesis in this paper. This table indicates that the probability that a distribution of hypertension like that found among these three groups would occur by chance is less than 1 in 1,000 (chi square = 16.1, $p<0.001$). From table 2, it is evident that, while mean ages were the same among the three groups, sex distribution differed significantly, with more females in the low-intake group. Although this difference probably is of no importance at these ages, the data were then analyzed for the 1,124 males, as shown in table 3. The findings remain essentially unchanged from those shown in table 1. Again there was a high degree of statistical significance to the distribution among the three groups ($p<0.001$). When tested against null value, the low-intake group had significantly less ($p<0.01$) hypertension and the high-intake group had significantly more ($p<0.02$) hypertension than would have occurred by chance alone.

The nutritional classifications of the 1,124 male subjects are outlined in table 4. There was no significant difference among the three salt-intake groups, however, the percentage of overweight or fat individuals (46.5%) among the males with hypertension, shown in table 5, exceeded that among the entire male population (26.8%) to a significant degree ($p<0.001$). For statistical analysis the four nutritional groups were combined into two: thin and normal became "non-overweight," and overweight and fat became "overweight." Comparisons then were made among individuals who were classified as having low or high salt intakes and who were overweight or non-overweight. Table 6 summarizes the significant differences found by such comparisons. The following conclusions may be drawn from the data in table 6: 1. Individuals who are not overweight but who are on a high-salt diet will have several times the incidence of hypertension found in similar individuals on a low-salt diet. 2. Among individuals who are on a high-salt diet, those who are overweight will have significantly more hypertension than will those who are not overweight. 3. Those individuals who are both overweight and on a high-salt diet will have a much greater incidence of hypertension than will individuals not overweight and on a low-sodium diet.

TABLE 3.—*Corrected Incidence* of Hypertension in Males Only*

Sodium Chloride Intake	Age, Yr.	Total Subjects No.	Total Subjects % of Total	Subjects with Hypertension No.	Subjects with Hypertension % of All with Hypertension	Subjects with Hypertension % of Intake Group
Low	36.8(± 9.4)	101	9.0	1	1	1
Average	36.1(±10.7)	522	46.4	38	39	7.3
High	35.7(±10.2)	501	44.6	58	60	11.6
Total	36.0(±10.4)	1,124	100	97	100	8.6

* For all three groups $\chi^2 = 14.3$ and $p<0.001$; for low intake group $\chi^2 = 7.42$ and $p<0.01$; for high intake group $\chi^2 = 5.54$ and $p<0.02$.

Comment

One important question still to be answered is whether the three salt-intake classifications used in this study have any relation to actual salt ingestion Originally [1b] it was thought that the classification might be useful for the low and high groups but that probably the average group would extend over the entire spectrum from low to high Some preliminary data suggest that this is correct A series of individuals from all three groups, with and without hypertension, has now been studied by collecting all urines for a minimum period of 7 days (and up to 38), from which an accurate index of sodium intake can be realized [6] From these data it is pertinent to note that the individuals with a low intake without hypertension had significantly lower urine sodium outputs (and therefore intakes) than the persons with hypertension, whatever the group into which the latter had been classified in this study Furthermore, the single subject with a low intake who was found to have hypertension had a urine sodium level like that of the other hypertensives, rather than similar to that of the other members of the low-intake group From these unpublished observations, it is likely that the following conclusions will emerge the arbitrary low-average-high classification based on the use of salt at the table, which was devised for exploration of a theory, probably is generally valid It will, however be subject to individual exceptions, because of the defects noted earlier in this paper However the data suggest that among those individuals who actually have a low-sodium diet, as measured by urine sodium level hypertension will be significantly less than among those people who have a high-sodium diet judged in the same fashion Therefore, the original thesis seems valid, namely, that there is a significant relationship between the level of sodium intake and the development of essential hypertension

TABLE 4 —*Nutritional Grouping of 1 124 Males*

	Sodium Chloride Intake								
	Low		Average		High		Total		
Nutritional Groups	No	%	No	%	No	%	No	%

Normal	62	61 4	314	60 2	[illegible]	57 0	662	58 9	
Overweight	20	19 8	112	21 4	116	23 2	248	22 1	26 8
Fat	3	3 0	26	5 0	24	4 8	53	4 7	
Total	101	100 0	522	100 0	501	100 0	1 124	100 0	

The question will be asked as to whether the enhanced salt intake of individuals predisposed to or with hypertension is caused by, rather than a cause of, the disease It has been suggested that persons with hypertension have an increased appetite for salt [7] The present report cannot exclude this possibility It may be pertinent to note, however, that for eight years one of us (L K D) has used drastic prolonged limitation of sodium (40-125 mg per day) in the study and treatment of patients in all stages of this illness This was done under metabolic ward conditions, without evidence of salt-craving, such as might be expected if excessive salt appetite were part of the disease Since many of these patients had been very heavy users of salt prior to such reduction, this probably is relevant to the present discussion

TABLE 5 —*Nutritional Grouping of Males with Hypertension*

	Sodium Chloride Intake			Total		
Nutrition Groups	Low	Average	High	No	%	
Thin		2	3	5	5 1	53 5
Normal		19	28	47	48 4	
Overweight		13	20	33	34 1	46 5
Fat	1	4	7	12	12 4	
Total	1	38	58	97	100 0	

It seems fairly well established that essential hypertension occurs more commonly in certain families than in others [8] If this represents true hereditary rather than common environmental factors, it does not mean that heredity alone is sufficient In rheumatic fever, for instance, hereditary factors are known to be important [9], yet, if streptococcic infections are avoided with prophylactic antibacterial therapy, rheumatic fever does not result [10] We would like to suggest that similarly, in the individual hereditarily predisposed to essential hypertension, the actual etiological agent is environmental, namely, the level of ingestion of salt In people without such hereditary predisposition, resistance to the effects of ingestion of sodium might be greater, but this resistance could be overcome by a greater ingestion over a longer period

The failure of many people on a high-salt diet to develop hypertension does not necessarily invalidate the proposed hyothesis With most disease inciting agents, exposures of apparently equal degree of *different individuals* will be followed by development of the disease in some but not in others Presumably in essential hypertension there are unknown factors that are of importance in modifying the effect of a given level of ingestion of sodium

It is known that overweight individuals suffer from hypertension more commonly than do non-overweight subjects [11] Could it be that in eating more food generally, more salt is ingested simultaneously? This is one possible explanation at least

TABLE 6 —*Statistically Important Difference* in Incidence of Hypertension in Males Only*

Non overweight subjects	
High sodium chloride intake vs Low sodium chloride intake	$X^2 = 7 2$ p<0 01
High sodium chloride subjects	
Overweight vs Non overweight	$X^2 = 10 8$ p = 0 001
Combination resulting in greatest statistical significance	
High sodium chloride intake overweight vs Low sodium chloride intake non overweight	$X^2 = 16 97$ p<0 001

---

* In each pair the first group has the greater incidence of hypertension The significance of the difference in incidence of hypertension was estimated by the standard chi square test

In view of the foregoing considerations, it is proposed that the level of sodium intake is the primary etiological factor in the development of essential hypertension

Summary and Conclusions

Among 1,346 adults who were classified according to their sodium chloride intake at the table, there were only 135 classed as having a low intake, while there were 630 and 581 in the average-intake and high-intake groups respectively The 105 persons with hypertension were distributed among the salt-intake groups in nonrandom fashion as follows low intake, 1, average intake, 43, and high intake, 61 Tested by the chi-square method, the probability of such a distribution of hypertension occurring by chance was found to be less than 1 in 1,000 The group with low salt intake had significantly less and the group with high salt intake significantly more hypertension than would be expected from random distribution

By dividing all individuals into overweight and non-overweight groups in addition to the sodium chloride categories, the following statistically significant ($p<0\,01$) conclusions can be derived 1 Individuals who are not overweight but who are on a high-salt diet will have several times the incidence of hypertension found in similar individuals on a low-salt diet 2 Among individuals who are on a high-salt diet, those who are overweight will have significantly more hypertension than will those who are not overweight 3 Those individuals who are both overweight and on a high-salt diet will have a much greater incidence of hypertension than will individuals not overweight and on a low-sodium diet The hypothesis is submitted that the level of sodium intake is the primary etiological factor in the development of essential hypertension

Chemotherapy of Renal Tuberculosis—An analysis of 219 consecutive autopsies in patients with tuberculosis since the introduction of modern chemotherapy reveals a striking contrast with the pre-chemotherapy findings Almost all of these patients had prolonged antituberculosis therapy with alternating courses of several drugs A number of observations in this series are worthy of note The real surprise, however, is the very low percentage of minimal tuberculous involvement While in 1028 autopsied cases without chemotherapy there were 279 with minimal lesions, in those with prolonged treatment with antituberculous drugs there were only 7 instances of military foci in 219 cases This point alone should prove the effectiveness of antituberculous chemotherapy in curing minimal lesions or preventing them at the end stage of hematogenous dissemination In this latter series, the patients with minimal renal foci and tuberculous involvement of the prostate were symptomless Of five cases with organ tuberculosis, four were symptomless, though all had intermittent pyuria There seems to be little doubt that minimal renal tuberculosis should be treated with chemotherapy However, a practical difficulty lies in the determination of the extent of the tuberculous lesion in the kidney The usual diagnostic procedure sometimes inaccurately delineate the extent of the disease Chemotherapy is indicated in every case of renal tuberculosis, although its effectiveness may be limited by the nature of the disase present Overall effectiveness has been marked and has been reported in several large series—A Sporer, M D , and G D Oppenheimer, M D , Renal Tuberculosis, *Journal of the Mount Sinai Hospital,* July-August, 1956

CLINICAL NOTES

CYSTICERCOSIS CEREBRI–CESTODE INFESTATION OF HUMAN BRAIN

REPORT OF A CASE OCCURRING IN LOUISIANA

John H Dent, M D , New Orleans

Invasion of the central nervous system of man by the larval form of the pork tapeworm is rarely encountered in the United States [1] and Canada, and previous studies from these countries have reported individuals who were former residents of known endemic areas However, in South America and certain countries of the Far East, the prevalence of cysticercosis cerebri is relatively high because of the greater frequency of intestinal infestation with Taenia solium in man This difference in prevalence is due in part to the fact that raw pork is not usually eaten in the United States and Canada and also that these countries have public health laws regarding the disposal of garbage and the inspection of meat for human consumption The purpose of this paper is to present a case of cerebral cysticercosis of the racemose type that was apparently contracted in Louisiana

Cysticercosis is caused by larvae of the cestode T solium The usual intermediate host, the pig, becomes infested with the parasite as a result of ingesting material contaminated with egg-laden feces The eggs hatch, and the larvae penetrate the wall of the pig's intestine, eventually becoming encysted in various sites, particularly the skeletal muscles

According to Faust,[2] man may become infested in a similar manner The sources of the eggs that humans ingest are (1) feces from a person who harbors an adult tapeworm (heteroinfection), (2) feces containing eggs that are transferred from anus to mouth by unclean hands of an infested person (external autoinfection), and (3) the small intestine, from which ripe eggs may be carried by reverse peristalsis into the stomach, where they are conditioned for hatching (internal autoinfection) The eggs hatch in the upper portion of the small intestine, and the larvae quickly penetrate the intestinal wall, entering the lymphatics and blood vessels They are then widely and fortuitously distributed and develop into cysticerci at the site of localization

The morphogenesis of cysticerci in the tissue has been described as taking place by a proliferation of the body wall of the larva together with central liquefaction and cavity formation A scolex develops and invaginates into the preformed cavity, giving rise to the so-called bladder worm In most locations within the host the cyst reaches its full size (about 1 cm in diameter) in approximately 10 weeks [3] The skeletal muscles, the chambers of the eye, and the central nervous system are the sites in which cysticerci most frequently are observed In skeletal muscle they excite a fibroblastic proliferation and are soon surrounded by a fibrous capsule These lesions eventually calcify Within the central nervous system, the larvae may localize within the leptomeninges or brain substance Localization within the parenchyma is followed by encapsulation and calcification Within the leptomeninges, a single cyst may develop numerous irregular projections that may extend into the brain parenchyma On section, such lesions appear multicystic or racemose The racemose type of cysticercosis develops in the leptomeninges overlying the brain stem and cerebellum In this location, projections of the cyst may extend for distances as great as 15 cm Within the brain parenchyma, individual larvae seldom produce lesions that exceed 1 cm in diameter

Dixon and Hargreaves [4] have established the importance of parenchymal cysticercosis cerebri as a causative factor of epilepsy in persons who previously lived in the Far East Wilson [5] has described the pathological changes that occur in the leptomeninges and brain parenchyma In addition, he emphasized the frequency with which these parasites form racemose cysts when they localize in the leptomeninges of the posterior fossa Bickerstaff [6] observed that the racemose lesion located at the base of the brain was more common in older subjects, whereas parenchymal involvement tended to occur in younger persons Within the parenchyma of the central nervous system the larvae may eventually become calcified and are then demonstrable roentgenographically As long as the larvae remain alive, only a minimal local inflammatory reaction is provoked The death of the larvae produces an intense local granulomatous inflammation in the leptomeninges, with foreign-body giant-cell reaction and fibrosis [7] South American authors have reported that in some regions approximately 25% of all hospital patients admitted with symptoms suggesting the presence of intracranial space-occupying lesions had, in fact, cysticercosis cerebri of the racemose type [8]

The neurological symptoms of cysticercosis cerebri occur late in the course of the disease,[9] but focal or localizing clinical signs rarely develop Increased intracranial pressure, which occurs in the racemose type, causes papilledema, headache, nausea, and vomiting Mental deterioration and personality changes are common in the advanced stages of the disease of both the parenchymal and racemose type

Diagnosis is difficult during the early stage of larval invasion, and cerebral symptoms are not a clinical feature Eosinophilia of the peripheral blood occurs only during the acute stage of generalized dissemination A history of the passage of tapeworm segments in the stool may suggest the diagnosis The cerebrospinal

---

From the Department of Pathology, Tulane University School of Medicine and Charity Hospital fluid may show a rise in the protein level and a pleocytosis that may be lymphocytic, neutrophilic, or predominantly eosinophilic during the early stage of central nervous system invasion When subcutaneous nodules are present, histological examination of the excised nodule reveals the intact Cysticercus During the early stage of dissemination, a microscopic study of a pepsin digest of excised muscle may reveal the larvae Months or years after the acute symptoms subside scattered focal areas of calcification within the brain parenchyma or striated muscle may be the only signs suggestive of previous infection The most frequent neurological symptoms at this late stage of the disease are epileptiform seizures and mental deterioration—usually, however, without evidence of increased intracranial pressure

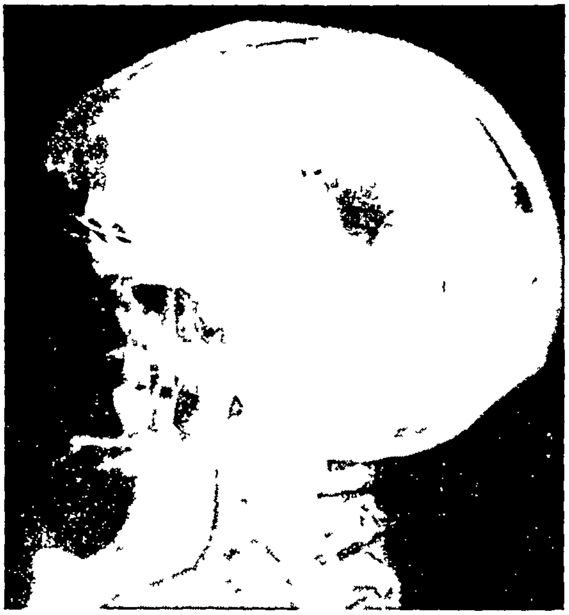

Fig 1 —Ventriculogram showing dilation of lateral ventricles

Report of a Case

History —A 44-year-old farmer was admitted to Charity Hospital Tulane University neurology and neurosurgery services on March 3 1954 with complaints of a slowly developing muscular weakness of the lower extremities urinary incontinence for the past month and periodic headaches of two years duration In the spring of 1951 he first noticed severe left frontal headaches of an episodic nature General physical and neurological examinations then had failed to reveal the cause and roentgenograms of the skull were normal

He did not seek further medical aid until the spring of 1953 at which time the severity of the headaches was markedly increased In the interim since the spring of 1951 his family had noticed regressive changes in his personality Spinal puncture at this time revealed a moderately elevated spinal fluid pressure, a mild pleocytosis and a slight increase in the spinal fluid protein level He was advised to enter the hospital but did not do so until September, 1953 at which time he refused further diagnostic studies and was discharged to the care of his physician After this hospital visit his condition deteriorated rapidly, and he became irritable voluble, and suspicious He displayed defects in judgment and impairment of memory He complained of muscular weakness of both legs and an increasing unsteadiness of gait His condition became progressively worse, and in November, 1953, he was forced to stop work as a result of his mental and motor difficulties In the course of the next three months he had several episodes of unconsciousness, although no convulsions were reported In the month before his final admission in March, 1954 he became disoriented at intervals, and nary incontinence developed

Prior to the onset of the illness in 1951, the patient had had no serious disease His family history was noncontributory He had never traveled outside the state of Louisiana except into Mississippi for a brief period

Physical Examination —On admission to Charity Hospital on March 3 1954, the patient was well nourished and did not appear to be acutely ill He was fairly well oriented His gait was ataxic Deep tendon reflexes were normal, and no abnormal reflexes were elicited Extraocular movements were normal The right pupil was slightly larger than the left Both pupils reacted well to light and had good accommodation There was bilateral papilledema of approximately 1 D Slight weakness of the upper and lower facial musculature on the left was present

Laboratory Data —Routine studies of the blood and urine showed no abnormal findings with the exception of a mild leukocytosis with a normal differential count The Wassermann reaction was negative Agglutination tests for typhoid paratyphoid A and B, brucellosis, and Proteus vulgaris strain OX 19, were negative Roentgenographic examinations of the skull revealed no abnormalities Electroencephalography demonstrated a small amount of generalized slow-wave activity and a prominent left frontal delta focus It was thought that the patient had a space-occupying lesion, probably in the left frontal lobe

First Operation —On March 16 a ventriculogram was done through biparietal trephine openings by Dr Murl E Faulk The intraventricular pressure was greatly increased Sixty cubic millimeters of clear fluid was removed and replaced with air X ray showed symmetrical dilatation of both lateral ventricles (fig 1) The third ventricle was poorly visualized, but it was possible to detect the outline of the fourth ventricle A bilateral Torkildsen procedure was done The posterior fossa was explored, and polyethylene catheters were passed from each lateral ventricle into the cisterna cerebellomedullaris No tumor was found in the posterior fossa

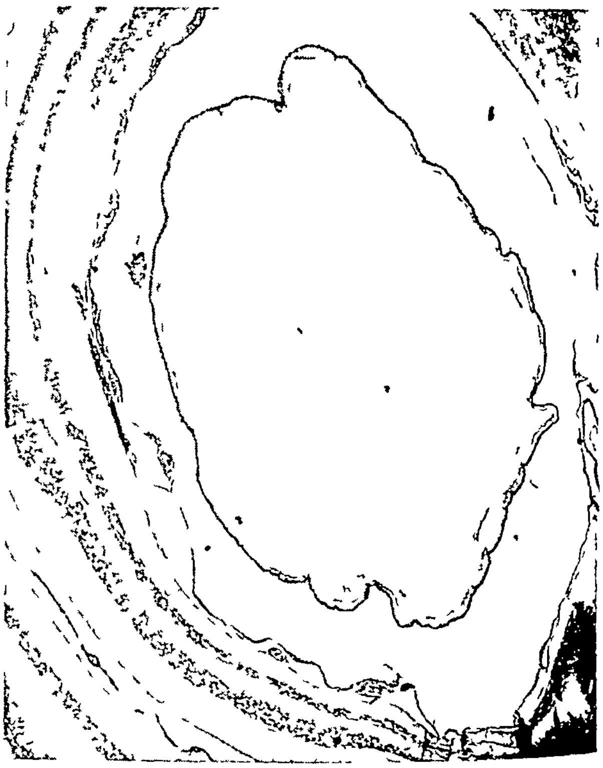

Fig 2 —Photomicrograph of cerebellum showing large cyst containing segment of parasite Note absence of inflammatory reaction in both leptomeninges and compressed cerebellar parenchyma Hematoxylin and eosin stain (× 14)

Subsequent Course —During the immediate postoperative period the patient s condition was critical but within three days it improved remarkably He became alert and was able to walk without difficulty His papilledema disappeared He continued to have a low-grade fever that had been present since surgery The fever did not respond to either chemotherapy or antibiotics

Six weeks after the first operation he became nauseated and vomited, and over a period of several days he became progressively more disoriented.

Second Operation.—In view of the rapid downhill course, he was returned to the operating room, and a pneumoencephalogram was performed on March 22, 1954. Air passed readily through the ventriculocisternal tubes that had been implanted at the first operation. It was impossible to outline the third ventricle in the ventriculograms. The third ventricle was explored through a right-frontal-lobe approach. Aside from symmetrical dilatation of the lateral ventricles and the anterior portion of the third ventricle, no pathological changes were demonstrated.

Subsequent Course.—After operation, the patient developed signs of medullary compression; he died on March 24, 1954, the second postoperative day. The final clinical diagnosis was of a space occupying lesion of the mesencephalon.

Autopsy Findings.—Autopsy was performed 1 hour and 20 minutes post mortem. The body was that of a well developed well nourished male measuring 5 ft., 5 in. (166 cm.) in height and weighing 130 lb. (59 kg.). The operative sites on the scalp corresponded to those described at surgery and showed no evidence of infection. Only the abnormal gross findings will be described.

The combined weight of the lungs was 1,000 Gm. The mucosa of the larynx and trachea was congested. Small emphysematous blebs were noted at the apex of both lungs. Areas of bronchopneumonia were scattered throughout all lobes. There was marked pulmonary congestion and edema. Examination of the gastrointestinal tract revealed no abnormalities except a superficial ulcer measuring 1.5 cm. in diameter on the anterior wall of the descending portion of the duodenum. No parasites were found in the gastrointestinal tract. The other thoracic and abdominal viscera were unremarkable.

Examination of the cranium and contents revealed the arachnoid to be smooth and glistening over both cerebral hemispheres. There was marked thickening of the leptomeninges at the base of the brain, overlying the undersurface of the pons, filling the interpeduncular fossa, and extending forward to the optic chiasm.

The weight of the fixed brain was 1,300 Gm. Over the anterolateral aspect of the right frontal lobe an irregular hemorrhagic defect was present measuring approximately 5 by 2 cm. and corresponding to the operative site. The defect extended into the anterior horn of the lateral ventricle and was surrounded by a narrow zone of hemorrhage. All sulci were narrowed and the gyri were flattened. The basilar artery was obscured by the intense fibrosis of the leptomeninges. The entire spinal cord was not examined, but the small portion removed with the brain was not remarkable.

When the brain stem and cerebellum were removed, it was found that the leptomeninges in the region of the peduncles were 2 to 3 mm. thick and contained numerous small cysts measuring from 1 to 3 mm. in diameter. These cysts contained clear fluid and were lined by thin, shiny gray membranes. Several cysts from 1 to 4 mm. in diameter were present around the periphery of the left cerebral peduncle. The aqueduct was completely occluded by what appeared to be clotted blood.

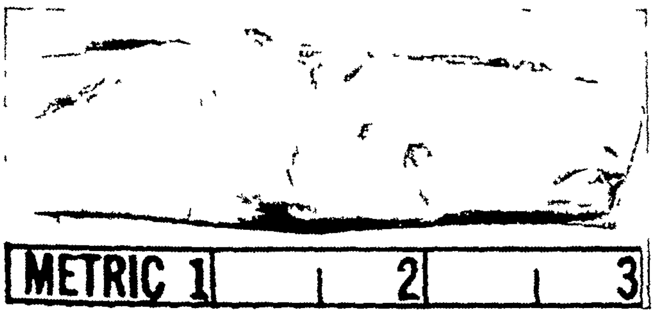

Fig. 3.—Section of thalamus, showing multiple small cysts. Glistening lining membrane is body wall of parasite, which has extended from leptomeninges into the parenchyma.

Multiple transverse sections through the brain stem and cerebellum revealed extensive fibrosis and thickening of the leptomeninges around the inferolateral aspects of the pons. Numerous minute cysts were present within the brain substance adjacent to the aquaeductus cerebri (aqueduct of Sylvius). Some of the cysts within the thickened leptomeninges were seen to extend into the substance of the vermis. A small cyst, approximately 1 cm. in diameter, was found overlying the left superolateral aspect of the roof of the pons. This cyst extended by continuity into the substance of the left cerebellar hemisphere (fig. 2). It was lined by a thin, pale, smooth, and glistening membrane. There was thickening of the leptomeninges around the foramens of Luschka.

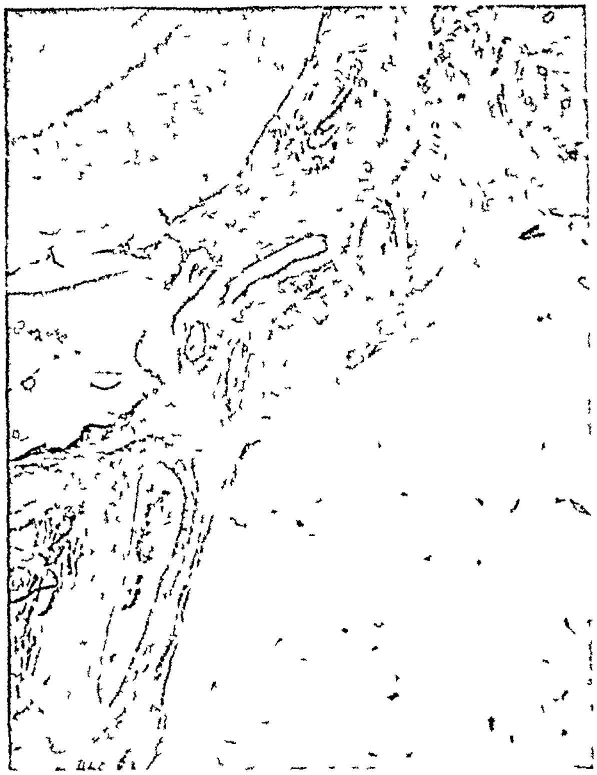

Fig. 4.—Photomicrograph of cerebellum and medulla, showing extensive fibrosis of leptomeninges with caseation and thickening of arterial wall. Hematoxylin and eosin stain (× 14).

Consecutive coronal sections through both cerebral hemispheres revealed the gray matter to have the translucent appearance characteristic of cerebral edema. There were scattered focal areas of hemorrhage in the gray matter of the undersurface of both temporal lobes.

The ventricular system was dilated except for the fourth ventricle, which was normal in size. The ependymal lining was roughened and opaque. Aside from the operative defect, the internal configuration of the cerebral hemispheres was normal. Numerous cysts varying in diameter from 1 to 5 mm., were present in a region extending from the hippocampus (Ammon's horn) medialward and involving a considerable portion of the left thalamus (fig. 3). Some of the cysts had a shiny gray lining membrane whereas in others no distinctive lining membrane was apparent. The anteroposterior extent of the area containing the cysts in the left thalamus measured approximately 1.5 cm. and many of the cysts were in close apposition to the posterior wall of the third ventricle.

Miscroscopic Findings.—All tissues were fixed in 10% formaldehyde solution. Selected sections from the brain were stained with hematoxylin and eosin, periodic acid–Schiff stain, Masson's trichrome stain, Giemsa's stain, and Wilder's stain for reticulum fibers.

Histologically, the heart, aorta, liver, spleen, thyroid, pancreas, pituitary body, adrenal glands, kidneys, and urinary bladder were normal. The lungs showed bronchopneumonia and pulmonary edema. A purulent bronchitis was present, and an organized thrombus was noted in a small pulmonary artery. In the duodenum there was a region of peptic ulceration extending into the muscularis and surrounded by chronic inflammation.

Numerous sections through the cerebellar peduncle showed a fibrous thickening of the leptomeninges, with heavy infiltration of plasma cells and lymphocytes. The small arteries were partially occluded by intimal proliferation There were scattered focal areas of caseation necrosis within the fibrotic leptomeninges (fig 4), about which a dense infiltrate of lymphocytes plasma cells, and macrophages was present Within the leptomeninges and extending into the brain parenchyma there were multiple cysts containing a cross section of a large parasite (fig 5) Further observation revealed that the numerous cysts within the leptomeninges and cerebral parenchyma were lined by portions of the body wall of the parasite Serial sections demonstrated that the body wall of the parasite formed the lining of the cysts in the leptomeninges and then extended by direct continuity to form the lining of adjacent cystic areas in the cerebral parenchyma thus forming the typical polycystic lesion seen in the racemose type of cerebral cysticercosis Grossly these cysts seemed to be separate and distinct Many of the blood vessels in the vicinity of the parasite showed perivascular round-cell infiltration with lymphocytes and plasma cells

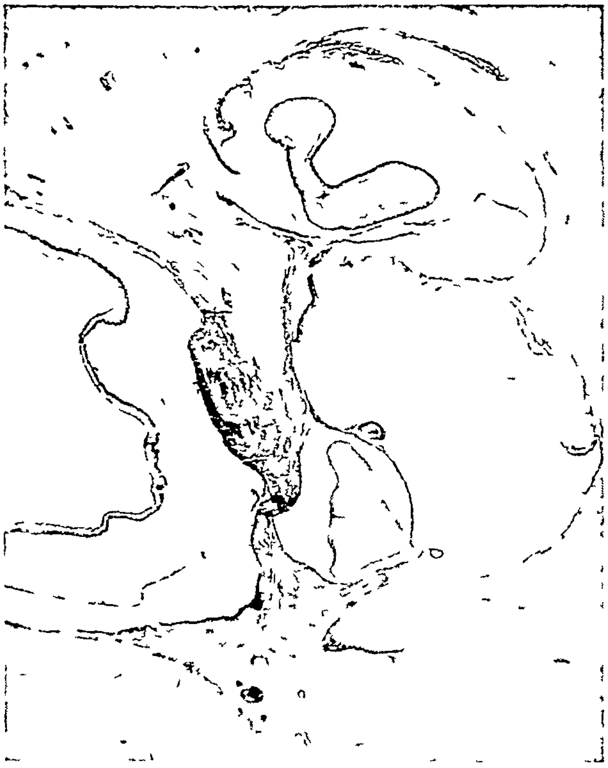

Fig 5 —Photomicrograph of hippocampus and leptomeninges, revealing multiple cysts three of which contain body wall of parasite Hemotoxylin and eosin stain (× 14)

A more detailed histological examination of the structure of the parasite (fig 6) revealed the body wall to consist of three layers (1) an outer compact cuticular layer (2) a thin intermediate cellular layer and (3) an internal reticular layer of varying thickness containing relatively few cells and lining the body cavity of the parasite Usually the meninges immediately adjacent to the parasite contained patches of caseation necrosis and granulomatous inflammation surrounded by dense fibrosis

On microscopic examination of the cystic lesions in the brain, the histological structure of the wall of the parasite was seen to be compatible with that of a Cysticercus No scolices or hooklets were found The typical multicystic lesion involving the brain stem (fig 3) and the microscopic appearance of the parasite (fig 6) also were compatible with a racemose cysticercosis

Similar histological findings were present in the hippocampus and the cerebral peduncle mesencephalon and thalamus About some of the cysts in the cerebellum there was only a slight reaction within the leptomeninges as well as a minimal glial response of the parenchyma Within the cerebral peduncle, intimal proliferation had partially occluded a large artery, and adjacent to this artery there was a small area of caseation necrosis surrounded by lymphocytes plasma cells foreign-body giant cells, macrophages and epithelioid cells

Sections through the cerebral cortex near the optic chiasm showed extreme fibrosis of the leptomeninges and scattered small patches of lymphocytic infiltration Scattered islands of heterotopic glial tissue were enmeshed within the fibrotic leptomeninges A small meningeal artery showed an obliterative endarteritis, and focal areas of encephalomalacia involving the gray and white matter were noted

The aqueduct was obliterated by dense glial tissue in which an area of hemorrhage was present (fig 7) A structure probably representing a degenerated fragment of the parasite was present within the region of reactive gliosis The blood vessels surrounding the obliterated aqueduct showed perivascular infiltration with lymphocytes and plasma cells Immediately underlying the aqueduct, within the leptomeninges, there were several large cysts that were lined by the body wall of the parasite and were surrounded by granulomatous inflammation and fibrosis

Periodic acid–Schiff stains of tissue sections containing the parasite showed the cuticle to be Schiff-negative, the cellular layer contained few Schiff-positive nuclei, while the nuclei of the cells of the reticular layer were Schiff-negative

Comment

The clinical features of this case were principally the typical signs and symptoms encountered with an expanding intracranial lesion, i e , headache and papilledema The neurological signs were not sufficiently definite to permit accurate localization The ataxia and muscle weakness were generalized and mild, without clear-cut cerebellar symptoms of dysmetria and dysdiodochokinesia The facial weakness was so slight as to be questionable, and the pupillary inequality was minimal, with reaction to light and accommodation intact Thus, it would seem in retrospect that the clinical signs should have suggested a lesion involving the brain stem and cerebellum The urinary incontinence was late in onset and may have been nonspecific, since it occurred in association with profound personality changes

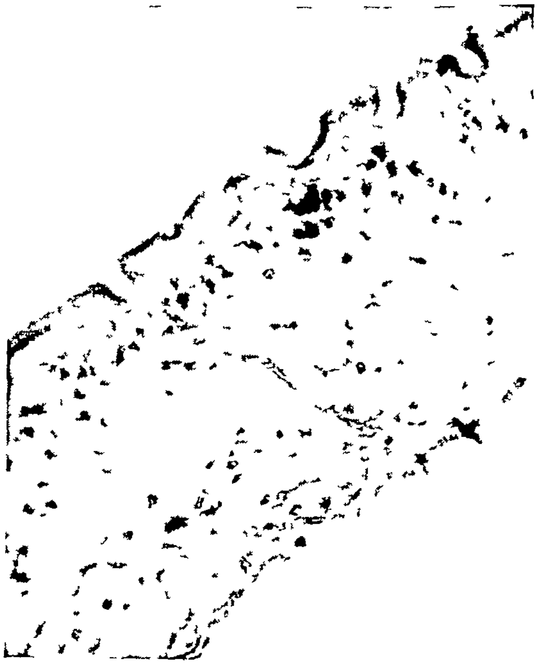

Fig 6 —Higher magnification of parasite shown in figure 5 showing characteristic three layers of body wall, outer cuticular layer, thin intermediate cellular layer, and internal reticular layer Hematoxylin and eosin stain (× 480)

The larval form of cestodes that may invade the brain and produce lesions somewhat similar to those of cysticercosis are Echinococcus granulosus, Multiceps multiceps, and the spargana of several species of Diphyllobothrium [10] Human infestation with the larvae of E granulosus and M multiceps occurs from accidental ingestion of dog feces Human infestation with the sparganum results from consumption of water containing infected Cyclops organisms, from eating uncooked snakes and possibly other animal hosts, or from applying such animal tissue to open wounds Histologically, the findings in this case in no way resemble those in hydatid disease, in which a characteristic laminated membrane forms the cyst wall M multiceps forms in its larval stage not a Cysticercus but a Coenurus Intracranial coenuri grow to considerable size (3 cm or more in diameter) Each Coenurus contains many scolices, which project from the wall into the cyst cavity In cysticercosis, however, each cyst has only one invaginated scolex, in the racemose type, usually no scolex is demonstrable Histologically, the body walls of a Cysticercus and a Coenurus are indistinguishable Morphological differentiation of these two cestode larvae in the brain rests largely upon the size of the parasites and principally upon the presence or absence of multiple scolices Becker and Jacobson [11] have stated that, in all cases, parasitic infestation of the racemose type occurring in the posterior fossa is due to the Coenurus form of M multiceps rather than to cysticerci The multicystic lesion involving the brain stem and the histological appearance of the parasite in this case are similar to those reported by Becker and Jacobson,[12] with the exception that scolices were not found in the present case Although the cestode described in this report could not be classified specifically on morphological grounds, the absence of multiple scolices suggests that the parasite was the larva of T solium

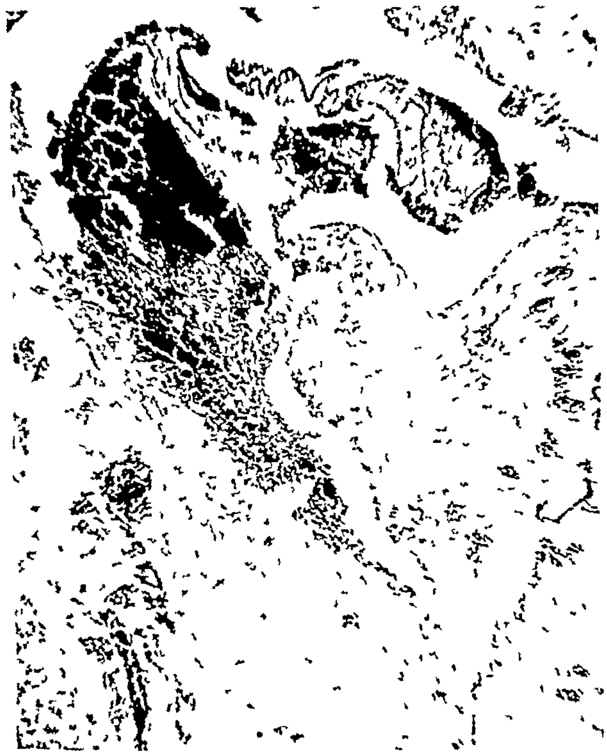

Fig 7—Photomicrograph of aqueduct showing obliteration by glial proliferation in which an area of hemorrhage is present Hematoxylin and eosin stain (approximately × 14)

Summary

A 44-year-old man died as a result of cerebral cysticercosis of the racemose type contracted in the United States No scolices or hooklets were demonstrated microscopically, but the parasite was tentatively identified as the larva of Taenia solium The larval form of this cestode can produce a granulomatous reaction within the leptomeninges sufficiently severe to interfere with the free flow of cerebrospinal fluid In this case, the aqueduct was obstructed and parasitic cysts were present in the adjacent tissues, as well as in the substance of the thalamus, in the cerebellum, and in the gray matter of the hippocampus (Ammon s horn) A chronic proliferative basilar leptomeningitis was present The resulting increased intracranial pressure produced a clinical picture suggestive of a space-occupying lesion Cysticercosis cerebri is rare in the United States and Canada, but it should be included among the less common conditions that can give rise to the signs and symptoms of an expanding intracranial lesion

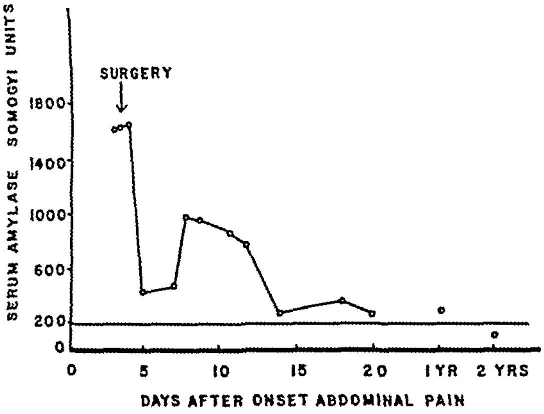
Lewison[7] found "mild but persistent increase in serum amylase activity in a patient treated surgically and found to have a ruptured Graafian follicle" In 37 patients with other gynecologic conditions, however, normal serum amylase values were found

The effect of morphine in occasionally causing increased serum amylase levels, by virtue of its spasmogenic action on the sphincter of Oddi and its contiguous musculature, is well recognized and has been studied intensively by several groups of investigators[8] Although the subject is still somewhat controversial, the view is held by some[9] that, for an opiate to produce an increased serum amylase level, *it is necessary* to have stimulation of the extrinsic secretions of the pancreas by either a meal or administration of secretin, in addition to the excitant action of the opiate on the sphincter of Oddi

The patient described in this report did not eat for at least 36 hours prior to administration of the single dose of morphine given, so there was no alimentary stimulation of pancreatic secretion There was also a substantial rise in the serum amylase level to 980 Somogyi units five days after the operation, without further administration of narcotics Furthermore, no increase in serum amylase level developed after a test injection of 0 01 Gm of morphine sulfate two weeks after the operation The patient had no evidence of impaired renal function, which may cause increased levels of serum amylase due to a decrease in urinary excretion of the enzyme[1c]



Serial serum amylase determinations in a 22 year old woman with a ruptured ectopic pregnancy

Generalized peritonitis may also cause a rise in the serum amylase level, possibly because of secondary inflammation of the pancreas[1c] However, a rise due to absorption of amylase from the digestive ferments released into the peritoneal cavity, such as occurs with a perforated peptic ulcer, is another mechanism which has been suggested to explain this phenomenon[10] The effect of peripancreatic inflammation as well as of absorption of enzymes from the peritoneal cavity on serum amylase levels has been the subject of experiments on dogs,[11] with the latter theory perhaps gaining adherents in recent years In our patient there was only blood contaminating the peritoneal cavity, making the idea of absorption of amylase from this site unimportant It seems possible that peripancreatic inflammation due to the blood may very well have occurred Raffensberger[1c] found mild elevations of serum amylase levels in two patients with stab wounds of the abdomen without perforation of the intestine and in one patient with hemoperitoneum The highest value was, however, only 405 mg per 100 cc

A possible explanation, and a not entirely convincing one, for the substantial elevations in serum amylase level found in the patient described in this report is that secondary inflammation of the pancreas occurred due to blood released from the ruptured tube, with spasm of the sphincter of Oddi caused by administration of morphine playing a contributory role

Summary

High concentrations of serum amylase, compatible with acute pancreatitis were found in a patient with a ruptured ectopic pregnancy There was no evidence of intrinsic pancreatic disease Two years after the ectopic pregnancy, the patient was in good health, with no abdominal pain and a normal serum amylase level

ELEVATED SERUM AMYLASE LEVEL ASSOCIATED WITH RUPTURED ECTOPIC PREGNANCY

Maurice L Kelley Jr, MD, Rochester, N Y

Serum amylase level determinations provide one of the most specific means of making the diagnosis of inflammatory disease of the pancreas However, it has been well established that increased concentrations of serum amylase may be produced, perhaps indirectly, by a variety of other conditions not associated with intrinsic pancreatic pathology The list of such conditions is long and includes perforated peptic ulcer, peritonitis, acute gallbladder disease, choledocholithiasis, biliary dyskinesia, dissecting aneurysm of the aorta, pneumonia, bronchogenic carcinoma, intestinal obstruction, uremia, and mumps (whether or not pancreatitis is present)[1] They may also occur after the injection of morphine or codeine In these conditions, however, the levels of serum amylase are rarely of the same magnitude as those attained in the early phases of acute pancreatitis, and they usually do not exceed 400[1b] to 600[2] Somogyi units

In the case to be described, much higher levels of serum amylase were found in association with a ruptured ectopic pregnancy The protean nature of the clinical picture in this disorder as well as in acute pancreatitis makes this finding of considerable importance to all clinicians dealing with abdominal emergencies

Report of a Case

A 22-year-old Negro woman with a chief complaint of abdominal pain of three days duration, was admitted to the Strong Memorial-Rochester Municipal Hospitals The patient gave a most confusing and unreliable history As well as could be determined, she had been experiencing crampy generalized abdominal pain of slowly increasing severity for three days The only associated symptoms were weakness, nausea, belching, and vomiting She was unable to give satisfactory information regarding her menstrual periods, but thought that menstruation for the present month was four or five days overdue The patient was afebrile and, except for a pulse rate of 130 beats per minute the vital signs were normal She appeared acutely ill and was writhing about in bed complaining of severe abdominal pain The scleras were not icteric The abdomen was rigid and extremely tender to palpation, with signs of peritoneal irritation There was no leukocytosis Urinalysis showed no abnormal findings

The cause of this abdominal emergency was not immediately apparent A serum amylase level determination was made using the Somogyi technique, and showed a marked elevation to 1,600 Somogyi units The normal value for our laboratory rarely exceeds 200 Somogyi units The serum alkaline phosphatase level was 26 Bodansky units (normal, 2 to 4 5) The blood for these determinations was obtained eight hours after a subcutaneous injection of morphine sulfate, 0 01 Gm, and atropine sulfate 0 0003 Gm had been given A serum amylase level determination made 15 hours after the injection showed 1 620 Somogyi units At this time the patient s abdomen was more distended and signs of acute blood loss had developed A posterior colpotomy revealed grossly bloody peritoneal fluid The serum amylase level of this fluid was 1,180 Somogyi units

The patient was taken to the operating room immediately and an exploratory laparotomy was performed by Dr George Trombetta Two thousand cubic centimeters of blood was present in the peritoneal cavity The source of the bleeding was a ruptured ectopic pregnancy on the right A salpingectomy was successfully done The gallbladder appeared normal Palpation of the liver and pancreas revealed no abnormal findings A total of 3 000 cc of blood was administered prior to and during the operative procedure The patient had an uncomplicated postoperative course and made an uneventful recovery No further narcotics were administered

On the day following operation the serum amylase level was still markedly elevated at 1,680 Somogyi units The serum lipase level was 0 24 cc (normal 0 2 to 1 5) and the serum alkaline phosphatase level had fallen to 4 Bodansky units On the second and fourth postoperative days the serum amylase level decreased to 414 and 460 Somogyi units, respectively but it rose to 980 on the fifth postoperative day (see figure) After this there was a progressive decline to almost normal levels

The patient denied having had any previous bouts of abdominal pain or other symptoms suggesting pancreatitis No calcifications were seen in a plain roentgenogram of the abdomen An oral cholecystogram showed good concentration of dye and was interpreted as normal A glucose tolerance test with 100 Gm given by mouth was normal A mumps complement-fixation test showed no significant titer, and there was no increase in titer on a return visit of the patient two months after the hospital admission No excess fat or starch in the stool could be demonstrated

Two weeks after operation the serum amylase level was 360 Somogyi units There was no rise in level after a subcutaneous injection of morphine sulfate, 0 01 Gm, was given as a test The patient was completely asymptomatic on discharge 21 days after the operation

One year later she was again admitted to the hospital for marsupialization of a Bartholin gland cyst There were no gastrointestinal complaints The serum amylase level was 300 Somogyi units Two years later the patient was seen in the outpatient department for a rectal complaint She denied having abdominal pain or other symptoms of pancreatitis, and stated that she felt fine' Physical examination was unremarkable The serum amylase level was 110 Somogyi units

Comment

The frequent difficulty encountered in making the diagnosis of ectopic pregnancy is well known It has been said[3] that the factor most typical of these patients is their atypical clinical picture When a clear history cannot be obtained, the problem is even greater Among the abdominal emergencies which may be mimicked are acute pancreatitis and the hemolytic crisis of sickle-cell anemia,[4] both of which were considered in the patient described in this report before the diagnosis became obvious after posterior colpotomy High levels of serum amylase compatible with acute pancreatitis such as were observed in this patient apparently have not been described previously in cases of ectopic pregnancy

Serum amylase is derived primarily from the pancreas and to a lesser degree from the liver, salivary glands, and possibly other glands[5] An increase in circulating enzyme is thought to be due to back pressure within the pancreatic ductal system, with retrograde passage of the enzyme through the capillaries into the blood stream[6] The mechanism responsible for the high levels of serum amylase in this patient, who had no demonstrable evidence of intrinsic pancreatic disease, is not clear

COUNCIL ON FOODS AND NUTRITION

Report to the Council

The following paper was presented at the symposium, "The Relation of Proteins and Amino Acids to Human Nutrition," in Los Angeles, May 21, 1956. This symposium was sponsored by the Council on Foods and Nutrition, with the cooperation of the Los Angeles County Medical Society and the School of Medicine, University of California at Los Angeles. This report is the third of the series, the others of which appeared in THE JOURNAL, *May 11 and May 18. After publication of the sixth and final report, this series will be available in monograph form.*

PHILIP L. WHITE, Sc.D., *Secretary*

AMINO ACID AND PROTEIN REQUIREMENTS OF INFANTS

Edward L. Pratt, M.D., Dallas, Texas

Man has been practicing nutrition since his appearance on this earth, yet in spite of this long interest in and association with foods, our present knowledge of human nutrition is limited. A great deal of prejudice, faddism, and crooked, illogical thinking clouds the whole field of nutrition. This state of uncertainty is in large measure unavoidable; it results from the complexities of the evaluation of nutrition, particularly in humans.

Nutrition plays an important role in pediatrics. Here physicians have a real opportunity to influence the eating habits and, therefore, the health of the nation. The cardinal principle of pediatric nutritional education is to make the eating of a wide variety of natural foodstuffs a pleasurable experience for the child and also for his mother. It is largely our ignorance of every essential food factor and our inability to specify adequate amounts of the known ones that make this principle a prerequisite for adequate nutrition at the present time.

Problems in Nutritional Experimentation

In order to appreciate the difficulties inherent in nutritional experimentation, let us briefly consider some of the steps that are essential in the evaluation of medical evidence.[1] A clear statement of the problem is necessary, but in nutrition is it possible to agree on the definition of such terms as "minimal requirement," "optimal allowance," or "optimal nutrition"?

The samples studied must be truly comparable in all relevant features. We know that the previous nutritional history and the initial nutritional state of the subject do affect the results of feeding experiments. The control of such factors in human subjects is understandably difficult. The allocation of subjects to different diets by random selection should be practiced in nutritional experiments.

In the "ideal" experiment a single variable can be manipulated at a time, but in nutritional experiments this is particularly difficult to achieve. Alterations in the composition of a diet with respect to amounts and types of carbohydrates, fats, minerals, and vitamins are known to influence the results. Uncontrolled intakes of food are frequently influenced by psychic factors that must be controlled in feeding experiments, especially in children.

In any experiment there should be a clear-cut method of assessment. In nutritional experiments what criteria are we to choose in assessing the results? Concerning protein nutrition, the limitations of the nitrogen balance method are well known. Gain in weight, since it may be due to the accumulation of fat, water, or protoplasm, may not serve as an adequate means of assessing the value of varying protein intakes. The chemical analysis of the whole body composition is not a feasible method of assessment when applied to humans. Increments of linear growth are useful if accurate measurements are taken and if other factors affecting growth can be controlled.

Before proposing a cause-and-effect relationship between the manipulated variable and the results observed, the results should be compared with the role that may have been played by chance or associated variables. Thus we see that even in a simple nutritional experiment the "experimental design" must be very carefully thought out. There is need for consistent definitions, uniform standards of assessment, and restricted interpretations of the data throughout much of the field of nutrition.

In the United States the problem of protein nutrition in infancy is different from that found in many parts of the world. Even today, the World Health Organization and the Food and Agriculture Organization consider the problem of protein nutrition first in order of urgency, especially in the construction of diets suitable for infants and children in the postweaning period. The interpretation of protein needs in terms of constituent amino acids is basic for an understanding of protein nutrition in health and for intelligent correction in defective dietary situations.

The intake of protein, as of most substances, is perhaps best viewed in the light of minimal requirements and maximal tolerated amounts. The upper limit of protein intake is determined largely by the size of the renal water requirement imposed by the high solute load that results from a high protein intake.[2] The high

---

From the Department of Pediatrics, University of Texas Southwestern Medical School and the Children's Medical Center and Parkland Memorial Hospital.

er the protein intake the larger the renal water requirement at any given urinary concentration In general, in the United States there is no need to know the minimal requirement of protein or amino acids for routine infant feeding, however, such knowledge is basic in planning food programs in areas with scanty supplies of dietary protein or in clinical situations in which the capacity to handle food is limited by illness or other conditions In these circumstances it is desirable to eliminate nonessentials in order to make room for the essential quantities of other substances This is particularly true when nourishment is given parenterally In addition, the knowledge of the amino acid requirements of healthy infants is necessary before a study can be made of these requirements as altered by disease Finally, because of current propaganda for supplementing diets with individual amino acids, the amino acid requirements for infants should be considered

Amino Acid Requirements in Infancy

A number of approaches to the determination of the amino acid requirements of infants are available One may use natural proteins that, by anaylsis, have been shown to be deficient in some particular amino acid Nature, however, has been singularly unobliging in providing a variety of such proteins In addition, the use of these incomplete natural proteins may introduce other amino acid imbalances in the diet One may use proteins in which individual amino acids have been degraded by chemical or other means The disadvantage of this method is that the nature and possible effects of the degraded fragments are unknown Apparently reasonable requirements for tryptophan, isoleucine, and the sulfur amino acids have been obtained by Albanese and co workers [3] by these methods

A synthetic diet in which the protein is replaced by an amino acid mixture may be used The advantage of these mixtures is that the ingredients are accurately known, although their absorption rates may be different from those of amino acids liberated from proteins In some studies the DL forms of the amino acids have been used, leading to uncertainties about the utilization of the D forms or their possible ill-effects on metabolism, in some diets the nonessential amino acids have been omitted The imposition of the synthesis of nonessential amino acids from the essential amino acids may or may not represent physiological economy

These difficulties and sources of error can be avoided by giving a diet in which the protein moiety is replaced by a mixture of pure amino acids, both essential and nonessential, all in the form of the natural optical isomers Such a synthetic diet has been used,[4] and its composition is shown in table 1 The amino acids were present in the diet in the same proportions as those found in human milk The data for the amino acid composition of human milk were taken from the tables of Macy and from the analyses of two samples of pooled mature human milk analyzed by column chromatography [5] This synthetic diet maintained normal growth in rapidly growing premature infants over periods of several days

In these experiments, infants, believed by all usual criteria to be in good health, were fed the full synthetic diet An individual amino acid then was generally reduced in amount or removed completely from the diet, and gradual increases in the quantity of the amino acid under consideration were made The nitrogen content of the diet was kept constant by adding equivalent amounts of glycine The patients were studied in the metabolism ward under the close supervision of clinicians and nurses specializing in metabolism The criteria of adequacy or inadequacy of a given amount of an individual essential amino acid were (1) alteration in the rate of weight gain, (2) change in the level of nitrogen balance, (3) analysis of the serum proteins, and (4) analysis of 24-hour specimens of urine for nitrogen and for amino acids by column chromatography

Threonine —The threonine requirements of eight patients ranging in age from 2 weeks to 4½ months were studied The requirements of two patients seemed to be met with 50 mg per kilogram of body weight per day, but the requirement of one patient appeared to be slightly above 60 mg of threonine per kilogram per day It was felt that the usual requirement for threonine could be regarded as roughly 60 mg per kilogram of body weight per day [4a]

	Gm	% of Total Calories
L Amino acid mixture	100	12
L Alanine	2 07	
L Arginine	4 69	
L Aspartic acid	8 78	
L Cystine	2 14	
L Glutamic acid	17 56	
L Glycine	2 06	
L Histidine	1 76	
L Isoleucine	6 11	
L Leucine	11 76	
L Lysine hydrochloride	7 10	
L Methionine	1 68	
L Phenylalanine	4 89	
L Proline	6 11	
L Serine	5 34	
L Threonine	4 58	
L Tyrosine	4 58	
L Tryptophan	1 68	
L Valine	6 64	
Hydrogenated vegetable fat	160	43
Dextrimaltose	375	45
Mineral mixture	22 3	
Vitamin B mixture	10 0 ml /day	
Vitamins A, C and D*	0 6 ml /day	

* Supplied as Tri Vi Sol by Mead Johnson & Company

Phenylalanine —In a similar manner, the phenylalanine requirements of six patients ranging in age from 1 week to 9 months were studied By the criteria used, it was found that approximately 90 mg per kilogram of body weight per day was the minimal phenylalanine requirement for these infants [4b]

Lysine —More recently Snyderman and associates [4c] have extended these observations to the essential amino acid lysine In a study of six infants they found the minimal requirement to be approximately 90 mg per kilogram of body weight per day

Comment —The values obtained by the method outlined seem reasonable on the basis of the consistency of changes in weight gain and nitrogen balance of all subjects The values for infants seem reasonable in the light of those obtained by Rose [6] for men and Leverton [7] and Jones [8] for women When calculations are made from the rather sketchy data available for infants fed measured amounts of human milk, the amounts of threonine, phenylalanine, and lysine calculated to have been ingested in human milk are more than the amounts required in the preceding experiments.

Recently Snyderman and co-workers[9] performed studies in which the quantity of protein, derived from cow's milk, was reduced in the diets of infants. The calories were replaced by carbohydrate and fat until a limit was found that would reduce normal weight gain. It was noted that protein from cow's milk could be reduced to as low as 4% of the total calories if an additional amount of nitrogen were provided by glycine or urea. On the lowest protein intakes with a glycine or urea supplement, the lysine, phenylalanine, and threonine intakes were of the same order of magnitude as the minima in the previously mentioned amino acid requirement studies.

Obviously, these experiments under quite artificial circumstances have many limitations. The requirements determined for the three amino acids probably would not be adequate if different criteria of adequacy were employed. They might well be altered if there were changes in the proportions of the amino acids, fats, carbohydrates, or vitamins employed in the diet, as well as any change in activity, rate of growth, or state of health of the patients. In addition, the small number of individuals studied does not allow for prediction of individual variations. Table 2 depicts the preliminary, tentative values for the amino acid requirements of infants as studied so far.

TABLE 2.—*Tentative Minimal Requirements for Essential Amino Acids During Infancy*

Amino Acid	Mg./Kg. of Body Weight/Day
Tryptophan	80
Isoleucine	90
Sulfur containing amino acids	85
Threonine	60
Phenylalanine	90
Lysine	90

Supplementation of Diets with Single Amino Acids

One should be wary of amino acid supplementation of diets without considerable thought and investigation of both the need for such supplementation and, particularly, the safety of such a procedure. In the adults studied, a deficiency of any one of the essential amino acids led to symptoms of anorexia, fatigue, and increased nervous irritability. In the infants, failure of weight gain was regularly observed. These common symptoms, which are in no way specific for amino acid deficiencies, occur in people with many other types of disability. Since we all occasionally lose our appetite and suffer from fatigue or nervous irritability, and since an unsatisfactory rate of weight gain is a comon pediatric complaint, one can see that there could be a tendency to exploit these symptoms and to begin adding amino acids to practically all foods.

This already is being done with lysine. The theoretical basis for this need is the assumption of a high value for the minimal requirement of lysine in infants.[10] This was determined by a method of questionable validity and resulted in the estimation of a minimal requirement of 170 mg. of lysine per kilogram of body weight per day, which is greater than the amount of [illegible] usually ingested daily in human milk and in some of the satisfactory low-protein infant foods made from cow's milk. It is much greater than that in the 4% protein diets supplemented with glycine or urea.[9] The minimal lysine requirement determined by Snyderman and others[4c] is about one-half of this value. One investigator has postulated that the total amino acid requirement of an animal of any age or species is determined by the proportions of the essential amino acids contained in the tissues being formed or metabolized. There is no evidence that the amino acid composition of the tissues being formed or metabolized in infancy differs remarkably from that in adults. The experimental evidence suggesting the need for lysine supplementation is based on a study of 15 infants and children with unspecified types of illness. Their changes in weight and in serum protein and hemoglobin concentrations were variable. This might be expected in an uncontrolled heterogeneous group. Hence, the results in the only published study of the rectification of growth failure by lysine supplementation are difficult to assess.[11]

Deleterious effects resulting from the addition of an excess of an individual amino acid have been reported. Amino acid imbalance is readily produced in tissue cultures, in animal experiments,[12] and in human beings. Therefore, it would seem highly undesirable to use such supplementation of proteins until more impressive evidence of their value and their safety has been produced.

Summary

Our knowledge of protein nutrition in humans is scanty and uncertain, largely because of the inherent difficulties in the evaluation of human nutrition. Therefore, those who must interpret nutritional experiments and give advice about diets to patients must exercise considerable caution. The present lack of knowledge makes it mandatory that pediatric patients be taught to enjoy eating a wide variety of natural foodstuffs. A plea is made for valid evidence before the procedure of supplementing proteins in the diet with individual amino acids is accepted.

FATS IN THE DIET

Wendell H Griffith, Ph D, Los Angeles

Report to the Council

The Council has authorized publication of the following report

Philip L White, Sc D, *Secretary*

The significant increase in life expectancy in the United States and the growing percentage of the total population in the over-65 age group have intensified interest in the nutritional problems of the aged Although it is doubtful if fundamental distinctions exist between nutritional requirements in middle and in advanced age, the distressing incidence of arteriosclerosis, coronary thrombosis, and cerebral vascular accidents has nevertheless raised questions about the possible relation of these diseases to the dietary habits of older adults and to the composition of common foods

Lipids are frequently designated as dietary culprits, and, in some circles, the terms 'fat' and "cholesterol' have become synonymous with atherogenesis and diaster How much is an optimal quantity of fat, and what should be its chemical nature? The fact that precise answers cannot be given to these fundamental questions emphasizes the urgent need for the reexamination of the role of lipids in nutrition

There can be no doubt about the physiological importance of fats The neutral fats are triglycerides of common fatty acids The high caloric density of fat and its insolubility in water make it superior to both glycogen and protein for the storage of energy, in both animals and plants Moreover, the deposition of fat in animals as adipose tissue insulates the body against rapid changes in environmental temperature and physically cushions organs and the body as a whole against external forces

That fat is not a foreign material in the body is indicated by the elaborate enzymatic and hormonal mechanisms that control its chemical transformations The interrelationship of these mechanisms with those concerned with the metabolism of sugars and amino acids suggests that the utilization of fat as a fuel is the usual, not the unusual, biochemical event Actually, much evidence exists to support the view that the intermediate products of fatty acid metabolism serve as the primary fuel of resting muscle It is significant also that fat is synthesized by mammary tissue and that it is quantitatively the most important source of energy in milk

Fats are widely distributed among common foodstuffs They add acceptability to meals, certain ones provide the essential fat-soluble vitamins, and their digestion and absorption make possible the intestinal absorption of these same vitamins

Storage fat may originate directly from food fat or indirectly from the conversion of dietary carbohydrate to fat During any 24-hour period starch sucrose, lactose, and glucose are assimilated through the digestive tract and are either burned or become, temporarily, blood glucose, liver or muscle glycogen, or tissue fat In a normally nourished individual a portion of the day's intake of carbohydrate is converted to fat If the individual is in caloric balance, this fat is burned between meals and during the night, and none is left in the tissues If the individual's caloric intake is excessive, his energy needs are satisfied without using all of the fat, and adipose tissues increase in amount

Fat formed from food carbohydrates in animals is largely a mixture of the triglycerides of palmitic stearic, and oleic acids These fatty acids predominate in butter fat, the fat of milk, and in the fat obtained from adipose tissue of farm animals Palmitic and stearic acids are saturated, whereas oleic acid is unsaturated, having one double bond in its carbon chain Tissue fats of animals may contain variable amounts of the triglyceride of linoleic acid if the fat trilinolein is present in the diet Linoleic acid, which is doubly unsaturated, either is not synthesized or is only slowly synthesized in animal tissues

In contrast to palmitic, stearic, and oleic acids, which, although useful, are dispensable in the diet, linoleic acid may be an essential nutrient It is an integral part of important tissue constituents such as lecithins and esters of cholesterol From a practical viewpoint, it is the dietary precursor of arachidonic acid, the polyunsaturated fatty acid that is indispensable to many animal species Although evidence for the essential role of linoleic and arachidonic acids in

---

Chairman Department of Physiological Chemistry, University of California Medical Center human diets needs further corroboration, prudence favors their provisional inclusion in the group of nutrients required by man

The problem of the nutritive value of the triglycerides of common fatty acids is complicated by the fact that man uses appreciable quantities of triglycerides of other and unnatural fatty acids in his diet This happens because of the commercial hardening of plant oils by the process of hydrogenation This procedure not only forms saturated bonds from unsaturated bonds but also may transform the natural "cis' isomers to unnatural "trans" isomers The latter have higher melting points but remain unsaturated Other unnatural isomers may result from a shifting of the double bonds along the carbon chain At the present time it is virtually impossible to describe chemically some of the commercial hydrogenated plant oils because of their complexity

Some plant oils such as corn, cottonseed, safflower, soybean, and peanut oils are rich sources of trilinolein As noted before, hydrogenation replaces a significant part of the linoleic acid with stearic acid and with unnatural, unsaturated fatty acids Arachidonic acid occurs in small amounts in some animal fats Olive oil, although unsaturated, is a poor source of linoleic acid, coconut oil, a plant fat, is saturated Chicken fat is an unusual animal fat because of its relatively large content of linoleic acid, fish oils are highly unsaturated and are characterized by other polyunsaturated fats in addition to some trilinolein These illustrations demonstrate the need of a more definitive terminology in describing the fatty acids in natural and in processed fats than is afforded by the general terms, animal or plant, hard or soft, saturated or unsaturated, and low iodine or high iodine number

Considerable evidence exists to show that, under certain circumstances, sources of linoleic acid may lower elevated serum cholesterol levels in man The evidence favors the concept that essential unsaturated fatty acids are required for the normal transport of cholesterol as lipoprotein and, possibly, phospholipid complexes Clarification of the circumstances under which hypercholesteremia can be prevented, however, remains to be delineated Valid experimentation has not yet determined the relative influence on serum cholesterol of surplus dietary calories, of an excess of the total dietary fat, of abnormal ratios of linoleic acid to other fatty acids in the diet, or of numerous other nutritive factors that may influence adversely the physical and chemical characteristics of lipids in the blood and in the walls of the vascular system Until a clear-cut solution of the problem of the prevention of arteriosclerosis and of its sequelae is forthcoming, it seems wise to assume that a faulty diet may be one of the causative agents Whether or not dietary fat is, in some fashion, the culprit remains to be proved In the meantime, one may recommend the dietary control required to attain and maintain optimum body weight and the choosing of a varied diet containing adequate amounts of those foods, including fats, shown by experience and by experiment to have special nutritive value

COMMITTEE ON COSMETICS

Report to the Committee

The following paper was presented at the symposium, The Rational Use of Cosmetics in Medical Practice, in Chicago, June 13, 1956 This symposium was sponsored by the Committee on Cosmetics, in cooperation with the Section on Dermatology, at the 105th Annual Meeting of the American Medical Association This is the third in a series of papers, the others of which appeared in The Journal, *March 2, page 740, and March 16, page 943*

ACTION OF EMOLLIENT CREAMS AND THEIR ADDITIVES

I H Blank, Ph D, Boston

Some confusion exists among physicians, pharmacologists, and cosmetic chemists as to just what constitutes an emollient For the purpose of this discussion, an emollient is defined as any externally applied material that tends to prevent or counteract the symptoms and signs of dryness of the skin Very mild dryness may be apparent only as superficial scaling of the skin, but severe dryness may be accompanied by considerable scaling, fissuring, inflammation, pain, or itching If emollients and dryness are so defined, it becomes apparent at once that the emollient creams and lotions produced by the cosmetic manufacturer and the simple emollient ointments and lotions prescribed by the physician have much in common Their functions are the same The cosmetic manufacturer and the physician probably can learn from each other

The majority of emollients, cosmetic or pharmaceutical, are mixtures of an oil and water In addition, an emulsifying agent is used to keep the oil and water well mixed, and a perfume may be added Any one or more of a large variety of oils may be used If the oil has a low melting point, the emollient will feel greasy

---

From the Dermatological Research Laboratories, Department of Dermatology, Harvard Medical School, Massachusetts General Hospital on the skin, if it has a high melting point, the residual oily film will not feel greasy Because it does not feel greasy, and because, as it is rubbed onto the surface, its color probably changes from white to colorless, it seems to "vanish " The external, continuous phase of the emollient may be either oil or water, that is, the emollient may be either a water-in-oil or an oil-in-water emulsion, depending on the type of emulsifying agent used When the continuous phase is oil, water is the dispersed phase and vice versa

After these emollients are applied to the cutaneous surface, some of the water may be taken up by the stratum corneum, but most of it evaporates into the air The nonvolatile oil of the emollient remains on the skin It has been assumed, therefore, that the residual oily layer serves as a "lubricant," since most of the emollients have the physical characteristics of lubricants In order to act as a "lubricant," the oil should locate between the lamellas of the stratum corneum, thus allowing the lamellas to slip over one another and permitting the skin to flex without breaking the stratum corneum With this in mind, attempts have been made to find oily substances that would penetrate the stratum corneum Lanolin and lanolin mixtures have been said to penetrate the skin better than do other oils, particularly petrolatum

Indeed, lubrication might be one of the mechanisms by which emollients act, but it does not seem to be the major mechanism involved It can be easily shown that neither an externally applied oil nor the natural oils can keep the stratum corneum flexible without the aid of water[1] If the cornified epithelium (a piece of callus or the top of a sunburn blister) is removed from the skin and allowed to lose its water but none of its natural oils, it becomes inflexible and brittle Immersion of this dry, brittle cornified epithelium in various anhydrous oils for long periods of time, even two or three years, will not make the cornified epithelium flexible again If the brittle callus is immersed in water, however, it becomes quite flexible in a very short time Currently, water is the only known plasticizer for keratinized tissue

The application of a film of oil to the cutaneous surface relieves the symptoms of dryness, however This film functions in two ways First, the oil replaces a roughened, scaly surface with a smooth film, and small spicules of cornified epithelium, which extend above the surface and produce roughness, are "cemented down" Thus, the cutaneous surface seems smoother Second, and more important perhaps, if the oily films are occlusive, they will retard the evaporation of water from the cutaneous surface and help keep the stratum corneum hydrated and flexible

The natural lipid film on the surface is not an occlusive barrier, and the major barrier in the skin is below the stratum corneum Winsor and Burch[2] showed that the natural lipids do not prevent water loss to the environment, and Rothman[3] stated that it is not difficult to get water into the stratum corneum from the environment through whatever lipid film there is on the surface In 1924, Rein[4] pointed out that the stratum lucidum and stratum granulosum are responsible for the impermeability of the skin to electrolytes Later Rothman[5] stated that, at this same anatomic position in the skin, the *Übergangsschichten* act as the barrier against the penetration of water molecules because the proteins in these layers are buffered at a pH corresponding to their isoelectric points and therefore take up a minimum quantity of water Szakall[6] showed that it is necessary to strip intact human skin six times with adhesive tape before the barrier is broken sufficiently to allow water to escape rapidly enough to produce a moist surface Quantitative measurements of the rate of water loss through pieces of excised human skin, which have been stripped various numbers of times, have been correlated with histological sections of the stripped skin and support the hypothesis that the major barrier against diffusion of water molecules is near the base of the cornified epithelium[7]

Thus, since the surface film of natural lipids is not an adequate barrier to prevent loss of water from the stratum corneum and because there is a barrier between the cornified epithelium and the underlying moist tissues, the cornified epithelium loses water to the environment more rapidly than it receives water from the underlying tissues It tends to dry out, but fortunately it is a hygroscopic material and does not dry out completely in atmospheres of normal or high relative humidity, however, when the relative humidity is low, as during the winter months, the stratum corneum may dry out, become brittle, and break or scale when flexed unless it is adequately protected by a film of occlusive oil The action of the simple emollients, therefore, is primarily a surface phenomenon, and possibly the importance of the penetration of the oil into the skin has been overemphasized An effective emollient must be so constituted that it will help the stratum corneum maintain an adequate water content

It is at once apparent that the thicker the stratum corneum, the less flexible it will be if and when it becomes dehydrated Not only does the water content of the stratum corneum influence the condition of the skin, but the thickness of the cornified epithelium also plays a role When the stratum corneum becomes thicker, the symptoms of dryness increase Physical stimuli such as friction and exposure to ultraviolet radiation, chemical stimuli, and certain pathological states thicken the stratum corneum On frequent exposure to warm solutions of a soap or detergent, the skin receives both physical and chemical stimuli Such a process might evoke thickening If thickening is abnormal because of an added external stimulus, it may be corrected just by removing this stimulus, but, if it is abnormal because of some diseased state and abnormal keratinization, correction may be much more difficult

Vitamin A

Some evidence suggests that vitamin A alters keratinization Fell and Mellanby[8] and Weiss and James[9] have shown that keratinization of epidermal cells from the chick embryo growing in tissue culture can be completely suppressed by the use of vitamin A Flesch[10] has shown that ethers and esters of vitamin A inactivate sulfhydryl groups of mouse liver homogenates and the sulfhydryl enzyme dehydrogenase and cause hair loss when externally applied to mice Other investigators[11] have stated that large oral doses of vitamin A correct the abnormal keratinization in such diseases as keratosis follicularis, keratosis pilaris, and ichthyosis

Reasoning that this effect is exerted directly on the end-organ and that therefore systemic administration would not be necessary, some physicians have applied vitamin A topically, and cosmetic manufacturers have used this vitamin occasionally in emollient creams

There is fairly good evidence[12] to prove that vitamin A can penetrate normal, intact animal skin, and Mandelbaum and Schlesinger[13] indicate a systemic effect after external application in humans It is probable that it penetrates intact human skin slowly and that only a small portion of the amount applied reaches the granular and Malpighian layers of the epidermis where any faulty keratinization might be corrected There is still little evidence, however,[14] to show that abnormal keratinization in skin diseases is altered by the external application of a vitamin A ointment any more than it would be altered by the application of the vehicle alone Very little evidence has been found to show that the use of cosmetics containing vitamin A is any more beneficial for controlling symptoms of dryness than are simple emollient creams not containing any vitamin A In support of this statement, a representative of the cosmetic industry, in 1954, commented on a paper by Conley[15] and said, "I agree with our able contemporary that there is some boloney being handed out in publicity on the need for and value of vitamins in skin creams

"Whether the vitamins help the skin or not is something that clinical trials can establish easily enough So it is hoped the industry has done the work, or if not, it should get started Methinks we have loads to learn about the skin'[16]

Estrogens

In discussing estrogens, perhaps it is not justifiable to ask whether they function only by increasing the emollient action of a cream The estrogens are said to cause hydration of the skin, but this refers to hydration of the dermis and not of the stratum corneum They are supposed to delay or reverse some of the changes that occur in the skin during normal aging, only one of which is dryness During aging, there are changes in both the epidermis and dermis The epidermis and stratum corneum do not become thicker with age, if they change at all, they become thinner There may be a decrease in the activity of the sebaceous glands, and less sebum may be produced As has already been indicated, however, the sebum is probably not the major factor in skin dryness Some atrophy occurs in the skin of elderly people, the entire skin feels thinner, and it is less elastic and less resilient Many elderly people describe their skin as "dry" The question arises as to whether these changes are reversible and whether they can be prevented From what is known of the action of simple emollients, it would appear that they could not prevent or reverse such changes in the aging skin

It is easy to understand why estrogens have been added to simple emollients in an attempt to control aging of the skin in women, for these changes in the skin occur at a time when the normal production of estrogen decreases Other physiological changes also occur at menopause, and it is asked whether simple replacement of estrogen will control the cutaneous changes, and, if so, whether this replacement can be accomplished by topical application of estrogen

It seems reasonably well established that estrogens can penetrate normal human skin[17] Because this is true, undesirable systemic effects from the topical application of estrogen creams might occur Scattered reports in the literature, such as that of Goldberg and Harris,[18] seem to support this point of view However, there is a dearth of evidence concerning the absolute rate of penetration of estrogen through normal and abnormal skin from various concentrations of estrogen in different types of vehicles More evidence is needed Most estrogen creams currently available do not contain more than 10,000 I U of estrogen per ounce When such creams are used according to directions, they appear to be free of any abnormal systemic effects[19] There is probably a factor of safety in a cream of this concentration Peck, Klarmann, and Spoor[20] state that concentrations of estrogens in excess of 50,000 I U per ounce may produce undesirable systemic effects Early fears of carcinogenic action of these cosmetics appear to be unwarranted[21]

When estrogens in suitable vehicles are applied to the surface of animal skins, the majority of reports indicate that there are some local effects on the skin as well as possible effects on distant organs[23] The response of human skin, however, may not necessarily be similar to that of animal skin when estrogens are applied, for evidence that cutaneous effects occur in humans is not as conclusive Most investigators who feel that they see histological changes in the skin of aging women agree that there is very little evidence of alteration of the skin of men or young women[24]

Much of the evidence in support of the alteration of aging skin by the local application of estrogens is histological[25] The changes that have been observed—thickening of the epidermis, extension of the papillae, increase in the amounts of elastic tissue and in the diameter of the collagen bundles—are difficult to quantitate Some of the changes may be due to the angle at which the histological section has been cut Much of this work seems to lack objectivity Seldom have the investigators used control sites of skin treated with the vehicle alone, and seldom have they made their observations on coded slides Goldzieher, Roberts Rawls, and Goldzieher[25a] did observe coded slides

Clinical evidence to support or contradict the opinion that estrogen creams delay or reverse the aging process in the skin is meager Any change is likely to be quite subtle and to develop slowly, thus, adequate controls are very important In one recent well controlled study[26] 27 women of various ages applied an estrogen cream to one side of the face and vehicle to the other side for a period of 91 days, no difference could be detected in the two sides of the face A decision as to whether the subjects of this clinical evaluation represent the type of individuals for whom estrogen creams might be effective and whether the conclusions are justifiable must await further observations of this kind

One should not dogmatically say at this time that the external application of estrogen creams does nothing to aging skin, but good clinical evidence to support a statement to the contrary is not yet available In 1948, Sevringhaus[27] said

> The whole field of percutaneous administration of estrogens has had very little systematic study by qualified investigators Systemic as well as local effects are involved A recent review of the local activity of the sex hormones presents but little helpful information on this part of the problem, but points out the unfortunate exploitation of the public by the purveyors of certain cosmetics The remedy for such undesirable methods of treatment lies in careful study of the field by the medical profession

Eight years later, there is less concern about possible systemic effects, but it is felt that the medical profession has not adequately responded to this challenge, and it has not been proved conclusively that the estrogen creams either do or do not affect the aging skin

THE COSMETIC PROBLEM

GUEST EDITORIAL

Arnold J. Lehman, M.D., Ph.D.

During the past several decades, the popularity of cosmetic preparations has increased so considerably that, at present, their general use has become almost a necessity for the average woman. As such, these preparations are leaving the realm of luxury items. This demand has led to the new use of many known substances and the development and extensive manufacture of new synthetic compounds for incorporation into such products. Unfortunately, carefully controlled research by competent investigators, particularly concerning the fundamental principles of skin properties and mechanisms and the related problems in skin pharmacology and toxicology, has not kept pace with the many new products and the claims made in their behalf.

Certain unobjectionable claims have been advanced for the efficacy of certain cosmetic preparations for mitigating skin dryness, hiding skin blemishes and wrinkles, and affording a continued healthy and youthful appearance to the skin. In recent years, however, the trend has been to advertise such products as being more than just cosmetics. Preparations that at one time or another have been misrepresented include hair growers or hair restorers, hair color restorers, dandruff removers, deodorants, lipsticks, cold creams and cleansing creams, and freckle removers. The claims proposed for these products include suggestions that they serve as skin foods, skin rejuvenators, nourishing creams, skin tonics, contour creams for bust development or bust reducing, wrinkle eradicators, and deep pore cleansers. To date, however, no conclusive evidence has been offered in support of many of these claims. For example, there is nothing known to science that will restore color to hair or cure early male baldness.

In accord with this recent advertising trend, a number of biologically active substances such as vitamins and hormones have been incorporated into cosmetic preparations. The claims for these preparations subtly hint at their therapeutic efficacy without actually stating so. Vitamin A supposedly enhances the appearance of the skin. Actually, however, the scientific literature contains no well-substantiated account to support the contention that cosmetics containing vitamin A are of greater value than those that lack it. Similarly, the incorporation of potent ingredients such as the estrogens is without adequate scientific justification. It has not been conclusively proved that estrogen-containing cosmetics have any beneficial effect on age changes, wrinkles, or blemishes. Reports have appeared in the literature to suggest that, after topical application of these products, sufficient absorption from the skin might occur to upset body activity. However, more evidence is needed on this point. The problem does not concern only the safety and efficacy of vitamins and hormones, it extends to the potential harm that indeed may follow the indiscriminate inclusion of other similarly potent chemicals in cosmetic products.

The need for increasing the scope and number of investigations relating to fundamental problems of skin physiology, biochemistry, pharmacology, and toxicology cannot be stressed too strongly. The report by Dr. Blank in this issue of THE JOURNAL (page 412) serves as an illustration of the types of basic study needed to help solve the cosmetic problem.

MEDICAL LICENSURE

The 55th annual report on medical licensure prepared by the Council on Medical Education and Hospitals appears in this issue of THE JOURNAL. Data are presented in the first section concerning the medical examination and the licensure of physicians in the United States and its territories and outlying possessions for 1956. In addition, the report summarizes trends in licensure over many years. Current regulations pertaining to medical licensure are also presented. The boards of examiners in the basic sciences are discussed in the second section of the report and, lastly, the National Board of Medical Examiners.

The report calls attention to the development of examination institutes by the Federation of State Medical Boards of the United States. This commendable effort aimed at uniformity, equivalence, and improvement in the quality of the licensing examination should result in a meaningful evaluation for fitness to practice medicine. The first institute held in February was devoted to the examination in obstetrics and gynecology, and a summarization of the program presented indicated "that the licensing examination should be one that would determine the candidate's appreciation of medical problems and his responsibility toward them at a point beyond the final evaluation by the medical school."

In 1956, a total of 14,543 licenses to practice medicine were issued by 54 boards authorized by law to grant licenses to practice the art and science of medicine. The 14,543 licenses issued last year represented 7,122 granted after a successful written examination and 7,421 granted by reciprocity and endorsement of state licenses or the certificate of the National Board of Medical Examiners.

Additions to the medical profession are reflected in a number of tables included in this study. There were 7,463 physicians who secured their first license to practice medicine and surgery during the calendar

---

Chief, Division of Pharmacology, Food and Drug Administration, Department of Health, Education, and Welfare, Washington, D. C.

year 1956 In the same year, 3,659 deaths of physicians were reported to the offices of the American Medical Association Thus, the physician population in the United States and its territories and outlying possessions was increased by 3,804

Failures by graduates of approved medical schools in the United States amounted to 4 5% and by graduates of approved medical schools in Canada 11 5% The percentages of failure in three other groups—graduates of foreign faculties of medicine, unapproved medical schools, and schools of osteopathy—were 43 2, 81 8, and 26 respectively

Provision is made by 33 boards for the issuance of temporary and educational permits, limited and temporary licenses, or other certificates of limited registration The terms for the issuance of these certificates vary and may apply to hospital training, to those ineligible for licensure who seek further educational training, for practice in emergency areas, or for regular practice until the next regular session of the licensing board when permanent licensure is granted The report further outlines the licensure requirements for interns and residents in hospitals, the states which require an internship for licensure, the preprofessional and professional educational requirements of each licensing board, the schedule of written examination dates and reciprocity meetings, medical license fees, licensure on government credentials, and annual registration requirements

A progress report pertaining to the Educational Council for Foreign Graduates, which is attempting to develop an evaluation service for foreign medical graduates, is included The study reveals that graduates of foreign medical schools were examined for medical licensure by 37 boards in 1956 Graduates of 213 medical schools and 5 licensing corporations were examined, representing medical schools in the Philippines, New Zealand, 16 South and Central American countries, 24 countries in Europe, and 13 countries in Asia More than 50 graduates of the universities of Havana, Munich, Bologna, and Mexico City were tested, and more than 20 graduates of 17 other schools were examined The number who were successful in these tests was 1,012 Failures numbered 771, or 43 2% of those examined There was a slight increase in 1956 over the previous year in the numbers examined, while the figure representing those who passed the examination in 1956 decreased as compared with 1955 During 1956 there were 852 foreign-trained physicians licensed who represent additions to the medical profession having secured their first license during the year Of this group, 834 were licensed after written examination and 18 by endorsement of credentials In a seven-year period, it was shown that 4,543 foreign-trained physicians were added to the physician population of the United States

That portion of the report pertaining to the results of examinations given by the 21 boards of examiners in the basic sciences reveals that certificates were issued to 6,107 candidates in 1956 Of these, 3,734 were granted after written examination and 2,373 by reciprocity, endorsement, exemption, or waiver The failure percentage for those reporting this information was 16 6 The basic science laws do not specify that a candidate reveal his school of practice No attempt has been made in this study to differentiate between the schools and the healing art represented by the candidates examined or certified

The last series of tabulations refers to the examinations given by the National Board of Medical Examiners The certificate of the National Board is recognized by the medical licensing authorities of the states, the District of Columbia, and the territories, with the exception of Arkansas, Florida, Georgia, Indiana, Louisiana, Michigan, North Carolina, and Texas There were 2,072 physicians who were certified as diplomates last year The largest number of candidates presenting the same type of credentials for medical licensure by endorsement last year were 3,109 diplomates certified by the National Board of Medical Examiners in 42 states, the District of Columbia, and the territories

This useful and informative study compiled annually by the Council is made available through the cooperation of the various examining and licensing boards, for their cooperation, the Council and THE JOURNAL wish to express appreciation

ADVANCES IN LICENSURE

In the past few years there has been an increasing interest in the Federation of State Medical Boards to improve and reevaluate the whole field of licensure The prime stimulus for this activity has come from two sources—the unanimous decision that a preliminary solution to the foreign-graduate problem had to be found, and the growing interest of the federation to relate itself more closely to the interests of medical education

The turning point in the foreign-graduate problem was reached when, in 1953, it was conceded that the management of the foreign graduate should be approached from a national level in developing a preliminary program The federation joined the Council on Medical Education and Hospitals, the Association of American Medical Colleges, and the American Hospital Association to create the Educational Council for Foreign Graduates, Inc Thus, for the first time, the federation and the other interested groups have determined that educational qualification shall be a prime consideration in dealing with the foreign graduate in the future Prior to this, there had been some experimentation with additional educational requirements in New York and Michigan which indicated the desirability of overcoming educational deficiencies The federation will maintain a strong interest in this direction in the future The state boards are now aware that physicians coming from all over the world present varying levels of educational attainment

Having made this degree of progress in the foreign-graduate problem, the federation has now turned to some of its more domestic problems It has become obvious in recent years that licensure had not reconsidered its position in respect to the advances in modern medical education The teaching institutes of the Association of American Medical Colleges proved to be an excellent pattern for the approach to the reevaluation of the licensing examinations In 1956, the federation ratified a resolution to establish examination institutes designed to improve the local, as well as the national, level of state board examinations It is also expected that the completion of the institutes will result in far wider acceptance of interstate endorsement of medical licenses.

A novel approach to the improvement of licensing examinations is the separation of educational and fitness testing. While this is a somewhat belated recognition of accredited medical education, it serves the purpose of creating a wider interest in medical education as well as a more accurate definition of what the licensing examination should be. In the first institute, determination of the candidate's understanding and appreciation of medical problems at a point beyond graduation from medical school was defined as an objective.

The federation has an expanding interest in all phases of the education of a physician. One paper on the 1956 program was on some aspects of preprofessional education. Recently the attendance of federation members at educational meetings has increased yearly. A number attended the first World Conference on Medical Education in London in 1953.

In looking ahead, licensure will interest itself in improved leadership, periodic evaluation of its position, more uniform thinking on the problems of discipline and narcotic addiction in physicians, improvement of public relations, closer relations with Canadian licensing authorities, and a better understanding of basic concerns. Through the *Federation Bulletin*, more information on the state of medical education in other countries will be provided.

Licensure has abandoned the static state, and it is dedicated to its responsibility in the dynamic progress of the medical profession.

CONVENTION DRUG SAMPLES

During recent medical conventions several unfortunate incidents occurred involving the distribution of drug samples. In one case, a boy about 10 years of age was found wandering alone through the technical exhibit, his pockets filled with almost two dozen bottles and envelopes of multicolored pills. What attracted attention to the lad was his eating one pill after the other. On questioning, he expressed his enjoyment of the candy coatings. Included in his cache was over 14 Gm. (200 grains) of barbiturates. In another such occurrence that eventually could have proved dangerous, a guard stopped a man leaving the exhibit floor, who had evidently just removed his identification badge. When asked to show his credentials, the man ran away, leaving two shopping bags filled with more than 200 samples of various drugs.

A third illustration points out still another cause for alarm. At the close of a moderate sized medical convention a few years ago, a survey was made of the three major hotels that housed the visiting doctors. How much of various products had been distributed during the course of the technical exhibit was known, and it was found that over 80% of the samples collected had been discarded in the wastebaskets of the hotel rooms.

The problem of how to give the doctor samples of pharmaceutical products in such a manner as will not endanger the public health seems to occur at every medical meeting. New attention has been focused by the Food and Drug Administration on this form of physician's sample distribution. While recognizing the common practice of distributing drug samples at medical meetings, Deputy Commissioner John L. Harvey recently reminded pharmaceutical manufacturers of their legal responsibility to insure that prescription drugs be available only to legally authorized persons.

Many physicians and the ethical drug companies are in agreement that letting the doctor see, feel, and then actually test a sample of a product, either on himself or on the proper patient, will supply the most convincing evidence of its efficacy. In addition, both groups are agreed that comprehensive pharmacological data on the drug should accompany the sample. When the physician receives a product by direct mail, it is usually accompanied by package literature. If the detail man delivers the sample, he not only can supply the package literature and reports of research studies but he can answer, or at least obtain answers, to the doctor's queries. In the convention hall, however, while there are usually representatives of the pharmaceutical houses available to provide information along with the sample, it is not unusual to find the samples piled up on the display counter, where they are easily accessible to nonmedical persons. It is this form of dispensing that is potentially hazardous.

There is another method of supplying professional samples to the practicing physician who attends a medical convention, one that has been increasingly adopted over the past few years. This is the use of the registration card that is completed by the doctor when he observes a company's exhibit. It seems, however, that many physicians are hesitant to fill out such a card because of the fear of being deluged by dozens of detail men immediately after the convention. It would appear, on the surface, that a simple solution to allay such apprehension would be to have the registration card include the statement, "Do you wish our professional representative to make a special visit? Yes___No___" On this same card could be a listing of available samples, allowing the doctor to designate his interests. While this method will also relieve the doctor of having to carry various packages from meeting to meeting, at the same time it puts an additional responsibility on the pharmaceutical houses to mail the requested product to the doctor's office within a reasonably short period of time.

There is no doubt that most pharmaceutical manufacturers are concerned over the problem of samples of potent drugs falling into the wrong hands. The Medical Exhibitors Association and the manufacturers have discussed repeatedly what can be done to keep the practice under control. For a convention of the size of the annual American Medical Association meeting, the problem assumes important practical significance.

In consequence of this, an official placard carrying the Medical Exhibitors Association insignia that announces the 'no sampling' procedure will be supplied to and may be used by any of the pharmaceutical companies who will be present as exhibitors at the forthcoming Annual Meeting of the A. M. A. in New York City. This sign will read

Welcome Doctor

INTRODUCTION

Statistical compilations regarding medical licensure are presented annually in the State Board Number of THE JOURNAL The report for 1956 constitutes the 55th annual presentation Data are included pertaining to (*a*) medical examining and licensing boards of the United States, the District of Columbia, and the territories and outlying possessions of the United States, (*b*) the boards of examiners in the basic sciences, and (*c*) the National Board of Medical Examiners

The computations presented are based on official records received throughout the year from all medical examining and licensing agencies of all states, Alaska, Hawaii, Guam, Puerto Rico, Virgin Islands, and the Canal Zone The figures for Connecticut also include data reported by the homeopathic medical examining board of that state The homeopathic boards in Louisiana and Maryland had no new licentiates last year By recent legislative action in Maryland, the homeopathic board, after investigation regarding the issuance of spurious licenses was abolished All licenses issued by this board were canceled Data are also included pertaining to the 21 boards of examiners in the basic sciences and, lastly, the National Board of Medical Examiners The Council and THE JOURNAL gratefully acknowledge their appreciation to those who have supplied these data as well as other records furnished throughout the year to the American Medical Association

EXAMINATION INSTITUTES

After several years of concentration on the foreign graduate problem, the Federation of State Medical Boards of the United States turned its attention in 1956 to the concept of reevaluating the licensing examinations Following the idea of the teaching institutes of the Association of American Medical Colleges, the federation appointed a permanent committee to develop a program of institutes to review the major areas of medicine involved in examinations given by state boards

The permanent committee recommended certain objectives which are aimed at uniformity, equivalence, and improvement in quality in the licensing examination One of the essential decisions involved the separation of educational and fitness testing and a clear understanding of what each of these divisions involves The effort will be made in the institutes to direct the licensing examination away from textbook questions and toward problem situations in the exercise of responsibility

The basic pattern of the individual institute will follow a program of analysis in a particular area covered by a licensing examination The first institute was in obstetrics and gynecology, given during the 1957 Annual Congress on Medical Education and Licensure Perhaps the basic question for each institute is, "What should be the type of examination best suited to this particular subject?" In the Obstetrics and Gynecology Institute, one of the significant conclusions reached was that the licensing examination should be one that would determine the candidate's appreciation of medical problems and his responsibility toward them at a point beyond the final evaluation of the medical

---

In the descriptive data reference is made to the total number of boards for which figures are reported The figures include the examining and licensing boards in the territories and outlying possessions and also the homeopathic board of Connecticut school This conclusion clearly divides educational and fitness testing by the introduction of the factor of responsibility as something of unusual value in the measurement of fitness

The institute idea takes for granted that the candidate's medical education has been satisfactory, and at the same time it recognizes that the student is restricted in using responsibility Thus, the objective of fitness testing is moved ahead to a point where there has been a more liberal exposure to responsibility and follow through in the definitive care of patients At the same time, examiners are cautioned not to pitch their questions at the level of advanced specialty training, since this is more properly the area for specialty board examinations

The examination institutes seem destined to improve the individual examiner by providing a better understanding of his responsibility It is also evident that the licensing examination will be improved in the general area of continuation education Publication of the final reports of each institute will serve as a reliable guide to future examiners appointed to boards

The motivation to reevaluate the licensing examination stems from the desire to have licensure assume a realistic role in modern medical education

MEDICAL LICENSURE STATISTICS

The tables referring to medical licensure present figures pertaining to the number of candidates examined, the number licensed, and the number who represent additions to the physician population Data are also included pertaining to the regulations for medical licensure both of physicians who secured their professional training in the United States and Canada, and of physicians educated in other countries The state boards are discussed first, followed by the basic science boards and the National Board of Medical Examiners

STATE BOARDS OF MEDICAL EXAMINERS

Licenses Issued

In 1956, 14,543 licenses to practice medicine were issued by 54 boards authorized by law to grant licenses to practice the art and science of medicine The number licensed by each of these boards by examination or by endorsement of credentials is shown in table 1 Of the 14,543 licenses issues, 7,122 were granted after written examination and 7,421 by reciprocity and endorsement of state licenses or the certificate of the National Board of Medical Examiners

Physicians certified in a given year after written examination were not in all instances tested in that year The licensing boards of 27 states, the District of Columbia, Alaska, Canal Zone, Hawaii, Puerto Rico, and the Virgin Islands require a year of internship for licensure The candidate for medical licensure in some of these states is permitted to write the examination before or while serving an internship and, if he is successful, the license is issued on completion of the internship Licenses are withheld in some states for other technicalities In general, also, the licenses of physicians examined in December are dated and issued in the early part of the following year Table 1, therefore, includes some data on physicians who were examined in 1955 and on a few who were examined in previous years The figures presented in this table will not correspond with succeeding tables that deal entirely with physicians examined for licensure within the year 1956 In tables 11, 12, and 13 can be noted the number of physicians who secured their first license in 1956 and who thus represent additions to the medical profession in the United States and its territories and outlying possessions

TABLE 1 –*Licenses Issued, 1956*

	Examination	On the Basis of Reciprocity and Endorsement	Total

Alaska	0	8	8
Canal Zone	0	3	3
Hawaii	17	17	34
Guam	0	4	4
Puerto Rico	46	14	60
Virgin Islands	0	0	0
Totals	7 122	7 421	14,543

Of the 14,543 licenses to practice medicine and surgery issued in 1956, both by examination and by reciprocity and endorsement of credentials, the greatest number (1,745) were issued in California New York licensed 1,355, while more than 500 each were registered in Florida, Illinois, Michigan, Ohio, Pennsylvania, and Texas Delaware, Idaho, Montana, Nevada, North Dakota, South Dakota, Vermont, and Wyoming issued less than 50 each The fewest (18) were licensed in South Dakota Among the territories and possessions, Puerto Rico licensed 60, Hawaii 34 Alaska 8 Guam 4, and the Canal Zone 3 None were licensed for private practice in the Virgin Islands There was a decrease of 297 in the total number of licenses issued in 1956 as compared with the previous year The decrease in the number licensed after written examination was 257 and by endorsement or reciprocity the decrease totaled 40

Totals of the physicians licensed for 21 previous years, and for 1956, by both examination and reciprocity or endorsement, are included in table 3 Beginning in 1936 there was a marked increase in the number of physicians licensed representing principally the licensure of foreign-trained physicians The increases in 1946 and succeeding years were the result of the increase in the production of physicians by the medical schools of the United States and Canada, the licensure of foreign trained physicians, and in the reciprocity and endorsement group the movement of physicians to other locations for practice In the 22-year period from 1935 to 1956, 252,156 medical licenses have been issued, 138,658 after written examination and 113,498 by endorsement of credentials

Candidates Examined

In table 2 are recorded data referring to applicants for medical licensure by 51 licensing boards[1] For each board is given the number who passed and failed, the medical school of graduation, the percentage of failures for each school as well as each licensing board, and the number of states in which graduates of a given school were examined Approved medical schools in the United States that are no longer in existence, foreign faculties of medicine, unapproved medical schools, and schools of osteopathy are not listed by name, but the numbers examined in these three categories are included after those for existing medical schools in the United States and Canada

Throughout the last calendar year 8,342 candidates were examined, of whom 7,179 passed and 1 163 failed The candidates represented graduates of 76 existing approved medical schools of the United States, 11 approved medical schools of Canada, 2 approved medical schools in the United States no longer in operation, 218 faculties of medicine or licensing corporations of other countries, 5 unapproved medical schools in the United States that are no longer in operation, and 8 schools of osteopathy Osteopaths who were granted the legal right to practice medicine, surgery, or both by the medical examining boards are included in these statistics Osteopaths in other states who were granted the privilege of special practice by other than medical examining boards are excluded from these compilations

Examination and reciprocity meetings are scheduled at frequent intervals by licensing boards in most of the states to facilitate licensure and to enable physicians to commence practice without undue delay Later in this study a tabulation is included giving the schedules for all states The publication of the dates for examinations and reciprocity or endorsement meetings is a regular biweekly feature of THE JOURNAL

Represented among the 8,342 examinees were 6,149 graduates of approved medical schools in the United States of whom 4 5% failed, 165 graduates of approved schools in Canada, with 11 5% failures, 9 who graduated from approved medical schools no longer in operation, all of whom failed, 1,783 graduates of faculties of medicine located in countries other than the United States and Canada, 43 2% of whom failed, 44 graduates of unapproved medical schools at one time in existence in the United States, with 81 8% failures, and 192 graduates of schools of osteopathy, with 26% failures

As in table 1, the 8,342 examinees do not represent an equal number of persons, since a candidate tested in more than one state in a calendar year is counted in each state If a candidate failed more than once in a given state within the year, however, he is counted in that state as an individual or a single failure Figures that show the number of individual licentiates added to the medical profession in 1956 are given in tables 11, 12, and 13

The University of Tennessee, a state university, had the greatest number of graduates for any one school examined for medical licensure in 1956 There were 231 graduates examined, of whom 136 were tested in Tennessee and 95 in 11 other states The greatest number examined from a private school was 175, representing Tulane University School of Medicine, they were tested in 13 states, with 104 being examined in Louisiana, where the school is located Twenty-seven schools each had more than 100 of their graduates examined for medical licensure in 1956 as follows

State and Municipal Schools	No of Examinees	No of States in Which Examinations Were Taken
University of Tennessee	131	12
University of Michigan	194	13
University of Illinois	167	14
Ohio State University	164	7

school are licensed by endorsement of the certificate of the National Board of Medical Examiners This is also true of other schools with small numbers of examinees

There were 165 graduates of 11 approved medical schools in Canada tested for medical licensure in 1956 by 29 boards The figures are given for each licensing board by school in table 2 and numbers examined by each board in table 4 Of the 165 candidates examined, 146 passed and 19, or 11 5%, failed

TABLE 3 —*Licenses Issued 1935 1956*

Year	Examination	Reciprocity and Endorsement	Total
1935	5 725	2 194	7 919

Total	165	146	19

Nine graduates of two approved medical schools no longer in operation were tested in two states, and none were successful Graduates of five unapproved medical schools were examined in three states and graduates of eight schools of osteopathy in 11 states Unapproved schools were represented by 44 graduates, of whom 9 passed and 35, or 81 8%, failed Of 192 osteopathic graduates, 142 passed and 50, or 26%, failed Graduates of 218 foreign faculties of medicine were examined by 36 boards There were 1,783 such graduates, with 771, or 43 2%, failures

Graduates of the University of Miami School of Medicine at Coral Gables, Fla, appeared for the first time in state board examinations in 1956 This school graduated its first class of doctors of medicine last year Twenty-four graduates were examined in Florida and two in Georgia, and all passed Graduates of the University of Puerto Rico School of Medicine also appeared for the first time before state medical examining boards last year Thirteen graduates were examined in five states, of whom two, or 15 4%, failed

Totals for the six categories are given in table 5 It will be noted that 4 5% of the graduates of existing *approved medical schools in the United States* and 11 5% of the graduates of Canadian schools failed The greatest number of failures fell within three groups foreign faculties of medicine, unapproved medical schools, and schools of osteopathy Those in these three groups registered by medical boards are separately discussed in later tables

Consolidated Results of Examinations

The combined results of two groups of examinations, the state medical board examinations and part 3 of the examinations of the National Board of Medical Examiners, are given in table 6 This table represents a comprehensive analysis of the performance of physicians from individual schools It will be noted that in some instances schools having failures before state licensing boards had few, if any, failures before the National Board

In 1956 there were 6,149 graduates of approved medical schools in the United States examined by state boards, of whom 4 5% (279) failed In the same calendar year 2,106 graduates of these schools were tested in the final examination of the National Board, and 12 failed In both groups, a total of 8,155 were examined, of whom 7,864 passed and 291, or 3 6%, failed

Of the graduates of Canadian medical schools, 11 5% failed state board examinations in the United States and one failed the National Board test Only 19 graduates of foreign medical schools were examined by the National Board, while 1,783 were examined by state boards The National Board did not examine in 1956 any graduate of an approved medical school no longer in existence There were also none examined by *the National Board in the unapproved medical* school or osteopathic categories There is no comparison to be made in the three groups last mentioned

The total of all candidates examined by state boards was 8,342, of whom 7,179 passed and 1,163, or 13 9% failed For both groups—state boards and the National Board—10,427 were examined, 9,251 passed and 1 176 or 11 3%, failed

Failures in Medical Licensure Examinations

Licensure failures in 1956 before state medical licensing boards are further analyzed in table 7 In this tabulation is given the number examined in each state the number who failed the examination and the percentage of failures

---

Some states have additional requirements for graduates of schools outside the United States and Canada.

+ indicates reciprocal or endorsement relationships have been established. indicates no reciprocal or endorsement relationships have been established. (See column— At the discretion of the board.)

1 1st P first papers required ⊕ in citizenship column indicates full citizenship required in other columns it implies a requirement

2 In most cases there is a small additional recording or registration fee

3 Year of practice after internship required

4 Internship accepted in lieu of one year's practice

5 Two years professional practice required

6 All applicants must be graduates of a medical school approved by the American Medical Association

7 Just preceding application

8 Not required if applicant has been in practice more than 5 years

9 Basic science certificate required either by reciprocity or examination in addition to basic science subjects of National Board

10 Canadian citizens are required to file first papers

11 Not applicable to citizens of Canada

12 Oral examination required when application is based on a licen e dated five or more years prior to filing application

13 No reciprocity

14 Oral examination required

15 Endorsement of National Board of Medical Examiners $35

16 Actual practice for a period of three years immediately preceding date of application

17 Practical clinical examination required

18 In lieu of its own examination certificate of National Board may be accepted in whole or in part

19 Minimum fee

20 Licentiates of California Colorado Indiana Iowa Kansas Massachusetts New York and Rhode Island accepted on reciprocal basis at discretion of board

21 Not required if country in which applicant is licensed will admit to practice citizens of the United States licensed to practice in some

---

Thirty-eight schools had less than 5% and 19 had between 5 and 10% failures among their graduates. There were 10 schools with 10% or more failures in state examinations. The over-all figures and percentages for failures are modified when included with the results of the final examinations of the National Board of Medical Examiners (table 6).

It can be noted, referring to table 4, that those states with high percentages of failures examine a considerable number of foreign-trained physicians. The one exception is Florida. This state has no reciprocal provisions for medical licensure, and physicians planning semiretirement in a more ideal climate seek licensure in this state. Many of these physicians graduated from medical school in the early years of the century and experience difficulty in writing examinations.

In general, state licensing boards require the applicant to receive an over-all average of 75%, and at least 60% in any one subject. In case of failure in not more than two subjects, the applicant is permitted a second examination within 12 months. A few states consider such persons as conditioned in the subjects in which they fail. Conditioned candidates are not counted as failures in these statistics. When their grades are raised after a successful examination, they are recorded among those who passed.

secretary of the licensing board of the state in which the physician is interested

---

state or on proof of requirements similar to those required by California for graduates of foreign medical schools

22 At discretion of Health Bureau

23 Oral examination required if applicant s state requires it

24 If the applicant passes the examination in the state from which he transfers after the completion of his internship no practice is required

25 May require oral examination

26 Internship accepted at the discretion of the board as the equivalent of two years practice

27 Fee $25

28 Fee same as applicant s state charges but not less than $50

29 A two year internship or a year of residency is accepted

30 Diplomates of National Board not required to have been in practice for three years

31 Same as required of candidates of state applyin for licensure

32 Not required for licensure by reciprocity

33 Reciprocity applicants only

34 Supplemental examination required in certain cases when accepting the examination of a state with whom reciprocal relations have not been established

35 Applicants issued certificates prior to October 1953 acceptable

36 Fee same as applicant s state charges but not less than $75

37 For matriculants after Oct 15 1937

39 Reciprocity extended at discretion of board to candidates whose qualifications would entitle them to admission to examination and who took examination equivalent to that required by this board

40 Permanent license withheld until completion of citizenship

41 At the discretion of the board

42 Graduates of foreign medical schools are not accepted for licensure by reciprocity

43 Reciprocity extended at discretion of board to states having comparable licensin requirements and which accept Colorado applicants on a substantially equal reciprocal basis

44 Consecutive years immediately preceding application

45 Graduates of foreign medical school not accepted

Of the 14,543 persons obtaining licenses in 1956, 254 failed state board tests before obtaining a license Of these 127 had one failure 55 had two failures 26 had three failures, and 18 had four or more failures Twenty-eight physicians had failures ranging from 5 to 12 in tests before securing licensure

Registration by Reciprocity and Endorsement

A summary of the reciprocity and endorsement policies pertaining to medical licensure is included in table 8 One state, Florida, requires all applicants for medical licensure to pass a written examination Hawaii and the Virgin Islands do not have reciprocal relations with any state, but Hawaii will endorse physicians certified by the National Board of Medical Examiners Twenty boards require applicants for licensure to obtain a certificate from the board of examiners in the basic sciences of the state In the section of this report pertaining to basic science boards is included a table outlining the reciprocity, endorsement, exemption, or waiver policies of the basic science boards

Twenty-seven states, Alaska, and Puerto Rico have reciprocal agreements with specific states In 23 states reciprocity is extended at the discretion of the licensing board Eighteen states, which have reciprocal agreements also have similar discretionary powers to endorse applicants from nonreciprocating states who present credentials that correspond with those required by their respective states in the year issued. Also in this table is a column indicating the recognition accorded the certificate of the National Board of Medical Examiners.

Additional requirements including professional practice, citizenship, oral examination, internship, and the fee for a license by reciprocity or endorsement, are also recorded. In some states physicians of Canadian birth are exempt from the citizenship requirement. This is indicated by footnote. Few states will accept graduates of foreign faculties of medicine on a reciprocal basis. Other requirements or exemptions are indicated by footnotes; footnote numbers are referred to in the column headed "Miscellaneous."

This chart will be made available in reprint form. It is helpful to physicians who are considering a change in location. The facts recorded in this table are intended to present merely statements of licensure policies. The information here given should be supplemented by direct communication with the licensing boards. A list of the executive officers in charge of medical licensure appears elsewhere in this report.

The procedure in issuing licenses by reciprocity or endorsement varies. Some states consider applications for licensure at any time, while others hold monthly, quarterly, or semiannual meetings. The policy in effect in each state is shown in table 24. In addition, THE JOURNAL publishes biweekly the exact dates when applications are considered.

In table 9 are presented data pertaining to the credentials accepted as the basis for licenses granted without written examination in 1956. There were 7,421 so registered on the basis of licenses issued by other boards, the certificate of the National Board of Medical Examiners, by special exemption, and by acceptance of service with an agency of the government of the United States.

California issued the greatest number of licenses by this method. In this state 1,255 were registered. New York licensed 1,019. Four other states licensed more than 275—Connecticut 297, Massachusetts 349, New Jersey 384, and Ohio 332. The largest number of candidates presenting the same type of credential were the 3,109 diplomates certified by the National Board of Medical Examiners.

There were 321 licenses that were issued in Illinois, 213 in Maryland, 223 in New York, 265 in Ohio, and 264 in Pennsylvania presented to other states for reciprocal registration. California, which issued the greatest number of licenses by reciprocity or endorsement (1,255), certified only 147 of its licentiates to other states. Figures for other states were fewer than 250. Thirty-four medical officers of one of the federal services received licenses by endorsement of military credentials in five states. Twenty-five were licensed by nine boards on the basis of a license issued in Alaska, Hawaii, or Puerto Rico, 20 by five boards on the basis of Canadian or foreign credentials, and three were licensed in the Virgin Islands by special endorsement for civilian practice.

In table 10 are reported the numbers from individual schools represented by the 7,421 reciprocity licentiates. Every approved medical school in the United States and the University of Puerto Rico had graduates licensed without written examination in 1956. All of the approved Canadian schools were so registered with one exception—the University of British Columbia. The 7,421 licentiates included 6,985 graduates of approved schools in the United States and Puerto Rico and 121 from Canadian medical schools. Licenses without written examination were obtained by 180 foreign-trained physicians in 26 states, and 24 graduates of approved medical schools no longer in operation were registered in 13 states. Twenty graduates of unapproved medical schools secured licenses in 9 states, and 91 graduates of schools of osteopathy were registered in 10 states. This table reflects the movement of physicians to states other than the one in which they obtained their professional training or in which they first established their practice.

Licentiates Representing Additions to the Medical Profession

The numbers of licentiates of 1956 who received their first license to practice medicine and surgery during the last calendar year and thus represent additions to the medical profession is shown in table 11. The compilation of this table includes candidates examined and licensed in 1956, some who were examined in previous years but whose licenses were withheld until 1956 pending completion of a required internship, citizenship, or other technicalities, and physicians not previously licensed in any state who were certified during the year on the basis of the examination of the National Board of Medical Examiners. The figures also include physicians licensed on the basis of government credentials, those who received Canadian licenses, and those licensed by special exemption. The majority represented are recent graduates.

There were 7,463 additions to the medical profession in the United States and its territories and outlying possessions. In 1956, 3,659 deaths of physicians were reported to the offices of the American Medical Association. Deducting the number of deaths in 1956 from the number of persons licensed for the first time, it will be seen that there was a net increase of 3,804 in the physician population last year.

Among the 7,463 licentiates representing additions to the medical profession in the last calendar year were 6,035 who secured their licenses by examination and 1,428 by endorsement of credentials. The majority of the latter were diplomates of the National Board of Medical Examiners.

The numbers of first licentiates, arranged in nine geographical divisions, are compiled in table 12. The geographical divisions representing the greatest number of additions to the medical profession were the Middle Atlantic States with 1,532, the East North Central States with 1,437, and the South Atlantic States with 1,210. More than 400 were added in each of five other groups: West North Central 824, Pacific 720,

Registration of Physicians, 1904-1956

A tabulation of total numbers of physicians registered for 53 years from 1904 to 1956, inclusive, is given in table 14. This study contains figures pertaining to the number of physicians examined and registered by written examination, the annual percentage of failures, the number registered annually by reciprocity or endorsement of credentials, and the total registered. The number of physicians registered annually from 1904 to 1933 shows slight fluctuation, except in 1918, when only 4,231 were licensed, the lowest registration in 53 years This decrease was due to a sudden withdrawal of physicians from civilian life in World War I After 1933 there was an upward trend, except during the years 1940 to 1943, inclusive The marked increase in 1943 was the result of the acceleration of the medical school curriculum and the efforts on the part of medical educators of the country to maintain a steady flow of physicians for both civilian and medical practice The greatest number of physicians registered in any year was in 1946 The licensure of medical officers by endorsement of credentials on their return from military service and the original licensure of physicians who had entered military service on completion of the internship accounts in large measure for the increase that almost doubled the registration of the previous year 1945

In the years since 1946, the numbers registered decreased annually until 1952, although they far exceeded the prewar totals The last four years has shown an increase in the number of physicians registered The number registered in 1956 was slightly lower than in the previous year

The highest percentage of failures was 21 7 in 1908 Many of the medical schools at that time were proprietary institutions operating for financial returns rather than the improvement of the medical curriculum Beginning in 1915, the percentage of failures began to drop, reaching a low of 5 7 in 1930 Beginning in 1936, the percentage of failures began to rise, reaching another peak of 20 7 in 1940 This was the result of the increase in the number of foreign-trained physicians seeking licensure in the United States, many of whom are not successful after repeated attempts at licensure examinations While the percentage of failures has been reduced somewhat in recent years, it still reflects the unsuccessful attempts of foreign-trained physicians, graduates of unapproved medical schools, and schools of osteopathy to secure licenses The annual failure rate among graduates of approved medical schools is about 4% This table again refers to examinations given annually rather than to individuals examined A candidate who fails more than once in a state in a given year is counted as one failure but, should he again fail in a succeeding year, this fact is computed among the failures for that year Likewise, a successful candidate securing a license in more than one state in a given year is counted in both states and likewise is counted if he passed examinations in later years The figures in this table give only a fair approximation of the number of physicians added to the profession

Graduates of Approved Schools and Others Registered, 1922-1956

In table 15, the numbers of physicians registered since 1922 are grouped in two categories, namely, graduates of approved medical schools and others In the computation of these figures, schools rated in classes A and B prior to 1928 by the Council on Medical Education and Hospitals of the American Medical Association are included in the first grouping In 1928, the classification of A, B, and C by the Council was discontinued, and a list of approved medical schools has since been maintained In the columns headed "Others" are included graduates of foreign faculties of medicine, class C graduates, osteopaths given recognition by medical licensing boards, and graduates of schools not approved by the Council subsequent to 1928

In 1956 there were 14 600 candidates registered, of whom 13,146, or 90%, were graduates of approved schools and 1,454, or 10%, were in the second group In the 35 years recorded in this table, 345,308 candidates were registered, including 311,416 (90 1%) graduates of medical schools indicated as in the approved group, and 33,892 (9 9%) others

Graduates of Unapproved Medical Schools Registered, 1952 1956

Recorded in table 16 are data regarding graduates of institutions that have not been approved by the Council on Medical Education and Hospitals of the

American Medical Association Figures are given for those licensed after written examination and those licensed by endorsement of credentials The table also includes a column combining the figures for these two groups They represent graduates of five unapproved medical schools, all but one of which are now extinct The latter institution has obtained the status of an approved school There were 216 graduates of unapproved medical schools registered from 1952 to 1956, inclusive, 80 by examination and 136 by endorsement of credentials California, Florida, Massachusetts, New York, and Texas licensed the greatest number of graduates of unapproved medical schools

Twenty-seven boards were represented in the five year period In 1956, there were 29 licensed by 10 boards, 9 by examination, and 20 by reciprocity or endorsement As can be noted, the numbers licensed are steadily decreasing

Graduates of Schools of Osteopathy Registered by Medical Examining Boards, 1952-1956

The number of graduates of schools of osteopathy granted the privilege of practicing medicine or surgery or both by 17 licensing boards from 1952 to 1956, inclusive, is given in table 17 There have been 1,296 such persons registered, 903 by examination and 393 without written examination In 1956, 12 boards licensed osteopathic physicians to practice Two boards admitted these graduates after examination and three by reciprocity, while seven boards licensed them after both methods Following is a summary of the actions and regulations of the 17 boards providing for the licensing of osteopaths by the medical examining board

In Colorado an osteopath receives a license to practice medicine In Connecticut any registered osteopath may obtain the right to practice medicine or surgery, or both, according to the type of examination taken Osteopaths in Delaware may be licensed as osteopathic physicians after successfully passing an examination in selected subjects The District of Columbia will permit any person engaged in the practice of osteopathy on or before Jan 1, 1928, to file application for a license to practice osteopathy and surgery Since 1952, in Illinois, graduates of the Chicago College of Osteopathy are examined and may receive medical licenses Under an amendment to the medical practice act in 1945, osteopaths in Indiana are permitted to practice medicine and surgery Persons who were licensed in osteopathy before 1945 are authorized to practice osteopathy, surgery, and obstetrics

In Massachusetts, for the purposes of registration, the D O degree is considered equivalent to the M D degree In New Hampshire, under the provisions of the medical practice act, osteopaths are granted the right to practice medicine and surgery The New Jersey medical practice act provides that an osteopath licensed prior to Nov 1, 1941, who has served for a period of two years as an intern or resident surgeon in an approved osteopathic or medical hospital, or has completed a postgraduate course of two years in a college of osteopathy or medicine approved by the board, or has had at least three years of practice in a hospital approved by the board, can be admitted to an examination in pharmacology, therapeutics, and surgery If successful, he can obtain a license to practice medicine and surgery

In New York, a law approved April 10, 1946, provides that any osteopathic licentiate who had obtained the additional right to use instruments for minor surgical procedures and to use anesthetics, antiseptices, narcotics and biological products, or any applicant who had met or would meet all the preliminary and professional requirements as of Sept 1, 1936, and has satisfactorily passed or would pass the regular licensing examination would be granted the right to practice medicine without limitation

The Ohio Medical Practice Act was amended in 1943 to provide that all graduates from osteopathic schools applying for the right to practice in the state must meet certain educational requirements and must pass certain examinations One of the required examinations is in surgery Those who qualify and pass all of the examination are then given a license to practice osteopathic medicine and surgery Those in practice and licensed under a more limited law in effect prior to 1943 can secure a license to practice osteopathic medicine and surgery by meeting certain additional requirements, including postgraduate work and the passing of several additional examinations

In Oregon, osteopaths who meet certain requirements are granted the right to practice in the subjects covered by the medical examination In South Dakota, osteopaths may be licensed to practice medicine, surgery, and obstetrics This is an unrestricted license Texas issues only one license, which is unrestricted in scope In Virginia osteopaths may obtain the right to use drugs and to perform surgery with instruments state may apply to take the same examination as physicians If successful, they will be granted licenses to practice medicine and surgery In Wyoming, the statutes contain no specific provision for the licensing of osteopaths The medical practice act provides that the certificate issued to all applicants shall be deemed a license to practice medicine in all branches in which the applicant has taken an examination

The Wisconsin law, amended in 1950, provides that an osteopath licensed in the state may obtain a license to practice medicine and surgery by completing a refresher course in materia medica and pharmacology consisting of not less than 64 hours of lecture and 60 hours of laboratory work and by passing an examination in these subjects Osteopaths not licensed in the

Preprofessional Training Requirements of Licensing Boards

In order to provide an opportunity for medical students to gain a broad educational background, the Council on Medical Education and Hospitals of the American Medical Association recommends four years of preprofessional college training Since January, 1953, the minimum requirement for admission to an approved medical school has been three years of college work, with the provision that rarely and only under exceptional circumstances will an approved medical school be justified in admitting a superior student with only two years of college preparatory work

* Association of American Medical Colleges and Council on Medical Education and Hospitals of the American Medical Association
x Implies yes
† 900 hours

The preprofessional requirements of medical licensing boards are indicated in table 18 Seven boards specify that no preprofessional requirement is mentioned in the medical practice act Twelve boards reported a three-year requirement In others, the law specifies at least two years of college work No board specifies in detail the number of hours that must be devoted to the subjects of the premedical curriculum, although seven boards report that this training must include certain subjects, such as English, physics, chemistry, biology, and a foreign language The candidates appearing for medical licensure are graduates of all years, and the seeming lack of conformity with accepted standards as promulgated by the Council on Medical Education and Hospitals of the American Medical Association and the Association of American Medical Colleges is due to the fact that initiation of the three-year minimum requirement for all candidates appearing for licensure would eliminate many graduates of earlier years In practice, the boards in granting licensure to a graduate of an approved medical school accept the premedical training required in the year the candidate was admitted to medical school

Professional Educational Requirements of Licensing Boards

The medical practice acts or board regulations of several state medical licensing boards specify the length of the medical school course In other states, the law or ruling specifies that the professional educational requirements included in the standards for approval of the Council on Medical Education and Hospitals of the American Medical Association or for membership in the Association of American Medical Colleges, or both, is the regulation for licensure Table 19 outlines the requirement of each licensing board The table does not record the internship that is a requirement for licensure in some states

[3] Three years for applicants matriculating after Jan 1 1954
[4] One year prior to 1919 two years subsequent to 1917 including courses in physics chemistry and biology
[5] Premedical training must include courses in physics chemistry biology English and a foreign language
[6] Three year college requirement
[7] For all applicants courses in physics chemistry and biology must be included in premedical training
[8] Premedical training must include courses in English physics chemistry and biology

Approval of Medical Schools

Seven licensing boards maintain their own list of approved medical schools in the United States and Canada Twenty boards require applicants for licen sure from medical schools in the United States and Canada to be graduates of medical schools approved by the Council on Medical Education and Hospitals of the American Medical Association One board requires that the medical school be a member of the Association of American Medical Colleges Twenty-six boards require that the schools be approved by the Council and be members of the Association of American Medical Colleges In the majority of instances the requirement is specified in the medical practice act or a formal regulation of the board In actuality, all approved medical schools are both approved by the Council and members of the Association of American Medical Colleges

Required Internships

There is currently no medical school in the United States which requires that the student serve an internship as a prerequisite to graduation Duke University School of Medicine specifies the internship requirement but does not withhold the degree until the internship is completed The degree is issued at the end of the four-year medical course, but the school obtains from each student a signed agreement that he will spend two years in training in a hospital or laboratory before entering practice

* Some states require the internship for graduates of medical faculties abroad and from reciprocity or endorsement applicants

† Internship must be a rotating service

* One-year rotating service or two years of straight internship or two year residency in a specialty

‡ Unless in active practice for four years

One year of internship, as a prerequisite to licensure, is required by the licensing boards of 27 states, the District of Columbia, Alaska, Canal Zone, Hawaii, Puerto Rico, and the Virgin Islands South Carolina reported the institution of this requirement in the past year Nine boards specify that the internship must be a rotating service Oklahoma, Vermont, and Hawaii reported that a one-year general rotating internship or two years of straight internship or two year residency in a specialty will meet the board's internship requirement Alaska will accept active practice for four years in lieu of the internship requirement Those licensing boards that require an internship for licensure are listed in table 20

Temporary and Educational Permits, Limited and Temporary Licenses, or Other Certificates Issued by State Licensing Boards

Thirty-three boards provide for the issuance of temporary and educational permits, limited and temporary licenses, or other certificates The terms for the issuance of such certificates vary This limited registration may apply to hospital training, to those ineligible for licensure who seek further educational training, or for regular practice until the next regular session of the licensing board A list of these states and information on the length of validity of this special registration are shown in table 21

TABLE 21 —*Temporary and Educational Permits Limited and Temporary Licenses, or Other Certificates Issued by State Licensing Boards*

Arizona	Temporary permits issued on basis of community emergency and subject to qualifying for regular license A regular license limited to full time practice in federal and state hospitals or institutions or federal state county or municipal public health departments exempt only in basic science certification is also issued
Arkansas	Temporary permit until regular board meeting
Connecticut	Educational permit issued for extension of education of graduates of unapproved foreign medical schools
Delaware	Temporary emergency license upon proven emergency one year subject to renewal
Georgia	Permit until board meets Institutional permits for one year
Idaho	To candidates holding certificate of National Board of Medical Examiners or licensed by written examination in another state until next meeting of board
Illinois	Temporary certificates for residency training for applicants who are not qualified for permanent registration
Indiana	Temporary license pending next examination for graduates of approved medical schools Temporary reciprocal license for six months
Iowa	Resident license valid in hospital approved by board for one year and may be renewed for additional three years
Kansas	Temporary permit until next board meeting Fellowships restricted to state institutions and state hospitals Doctor holding fellowship works under direction of the head of the institution
Kentucky	Temporary permits issued to applicants by endorsement and serve until investigations completed and meeting of board Limited licenses are for special place purpose and time
Louisiana	Temporary permit is granted to physicians possessing the necessary credentials who file application for examination or reciprocity and who locate in Louisiana in between the regular semiannual examination meetings of the board Temporary permit valid until next meeting of the board
Maine	Temporary licenses granted for residency training for one year and to camp physicians for ten weeks
Michigan	Temporary license for training program
Mississippi	Temporary permit for practice until next board meeting
Nevada	Temporary permit for one year for residency training within a specific hospital in Nevada
New Hampshire	Temporary license for five years to foreign physicians Permanent license issued upon becoming citizen of the United States
New Jersey	Temporary license for noncitizens Permanent license in six years may be extended an additional two years
New Mexico	Temporary permit for practice until next board meeting Special permit confined to institutional practice
New York	Temporary certificate for residency training for those eligible for examination in hospitals other than state and municipal institutions
North Carolina	Limited license issued for duration of residency
North Dakota	Temporary permit until next board examination
Oklahoma	Temporary licenses for residency training in approved hospitals
Pennsylvania	Postgraduate certificate issued for residency training
South Dakota	Temporary license issued for graduates of foreign Medical schools
Texas	Temporary permit issued until next board meeting
Virginia	Temporary permit issued until next board meeting and for service as a hospital resident
West Virginia	Temporary permits issued until next board meeting to qualified applicants and for practice within specified area until physician has an opportunity to appear before the board regarding permanent licensure
Wisconsin	Temporary permit for graduates of foreign medical schools not recognized by board for licensure
Alaska	Temporary permits issued while processing permanent licensure to summer cannery physicians and to physicians in the armed forces on short tours of duty valid for six months renewable an additional six months
Guam	Restrictive certificate to permit medical employees of federal contractors to practice in the discharge of their official duties
Puerto Rico	Provisional license to foreign graduates for one year Permit ceases on June 30 1957
Virgin Islands	Temporary certificates issued to military service personnel on duty and to municipal personnel until next license examination

Licensure Requirements for Interns and Residents in Hospitals

In general, physicians serving internships are not required to be licensed in the state in which the hospital where they are interning is located Wyoming and Puerto Rico have such a requirement New Jersey permits a service of two years without licensure and Florida a three-year service before licensure Other states have a requirement of registration with the licensing board or a stipulation that the physician must be eligible for licensure The states which require some form of registration for interns are listed in table 22

TABLE 22 —*Licensure Registration, or Other Requirements for Interns*

Licensure	Other Requirements
Wyoming	Colorado[1]
Puerto Rico	Florida
	Indiana
	Massachusetts[3]
	New Jersey[4]
	New Mexico[5]
	South Carolina[6]
	Texas[5]
	Virginia[7]
	West Virginia

---

[1] Registration with licensing board required annually not to exceed four years
[2] Must register every six months with state board of health and may serve for three years without licensure
[3] Limited registration for one year renewable annually for a period not to exceed five years
[4] May serve for two years without licensure
[5] Registration with licensing board required
[6] Must be eligible for licensure
[7] Graduates of foreign medical schools required to obtain permission from licensing board

[b] Endorsement of certificate of National Board of Medical Examiners $25

[c] Endorsement of certificate of National Board of Medical Examiners $10

Schedule of Written Examination Dates and Reciprocity Meetings

The schedule of dates for written examination and meetings or oral examination for the issuance of licenses by reciprocity or by endorsement of credentials is given in table 24 In most instances written examinations are scheduled twice annually and reciprocity meetings quarterly or as soon as the application for licensure can be processed In those states requiring a basic science certificate for licensure, dates of the examination or reciprocity meetings are arranged to coincide closely with the examination and meeting dates of the boards of examiners in the basic sciences A few states issue temporary permits enabling physicians to begin the practice of medicine until the board examination or meeting is held

Medical License Fees

Table 25 lists for each state, territory, and outlying possession the fee charged by the medical licensing board for registration by examination and also by reciprocity or endorsement of credentials The examination fee tends to be uniform, the majority of the boards charging a fee of $25 The fee for a license without examination varies from $20 to $200 Three states have a lower fee for those being certified on the basis of the certificate of the National Board of Medical Examiners than candidates licensed by endorsement of state licenses

TABLE 26 —*States Requiring Annual Registration*

State	Fee	State	Fee	State	Fee
Arizona	$ 5	Minnesota	$ 3	Tennessee	5

e Residents $2 nonresidents $5
f Residents $5 nonresidents $2
g Residents $10 nonresidents $5

Licensure on Government Credentials

Few states have provision in their medical practice acts for the acceptance of credentials issued by the federal government as a basis for licensure without examination Ten boards—Alabama, California, Delaware, Illinois, Pennsylvania, Texas, Utah, Vermont, Virginia, and Wisconsin—have indicated that in their discretion they may accept such credentials under varying regulations

Annual Registration

Thirty-nine boards require physicians to register their licenses annually or biennially This requirement applies in some states whether or not the physician is engaged in practice in the state In table 26 are listed the licensing boards that exact this requirement and the fee charged for such registration The fee charged

This summary should be supplemented by direct communication with the secretary of the licensing board of the state in which the physician is interested

x Implies yes

* Graduates of medical schools of Canada considered for licensure on the same basis as graduates of approved medical schools in the United States provided they comply with regulations pertaining to citizenship and internship

Additional Requirements

Alabama Candidate is eligible if he is certified by the National Board of Medical Examiners and approved

California Two year internship in an approved hospital in the United States one of said years being in California The foreign graduate must also pass the regular written examination given by the board prior to being eligible to intern in an approved hospital in California and pass an oral and clinical examination before a certificate may be issued

Colorado Accepted on basis of written examination only Credentials must be submitted in original form and accompanied by translation and will be directly verified or documents should bear evidence of being visaed by the U S Consul in the country wherein the school of graduation is or was *located*

Delaware Residence for one year required Completion of senior year in approved medical school in the United States

Illinois Approved rotating internship in United States required Limited license issued for practice in hospitals maintained by the state

Indiana Graduation from medical school approved by Indiana board plus repetition of senior year in approved medical school in United States or two years post graduate work in approved hospital in the United States Postgraduate work must be obtained in states other than Indiana

Iowa Internship or one year in medical school in the United States

Kentucky Applicant required to complete at least five years training in the United States in an institution approved by the board and to have successfully passed examination of National Board of Medical Examiners

Exemptions

District of Columbia Considered for reciprocal or endorsement registration on an individual basis

Illinois Graduates of European medical colleges or universities after Jan 1 1943 with the exception of certain approved colleges in the British Isles Denmark Holland Norway Sweden and Switzerland will not be accepted after July 1 1954 However graduates of such European medical colleges after Jan 1 1943 may be considered providing they present diplomas of graduation from approved medical colleges in the United States after attendance in such colleges for at least one year and in addition have served rotating internship of one year in an approved hospital in Illinois

Kansas Applicant must be licensed to practice in country of graduation Application must be filed one year in advance

Maryland Graduates of recommended medical schools may be accepted after completion of one year of internship or residency in an approved hospital in the United States if their credentials have been approved and they have presented at least two letters from medical authorities in the hospital recommending them as to their professional ability and moral character

Graduates not on the recommended list who obtained the medical degree after Jan 1 1940 are not eligible must serve three years in hospitals in United States and submit recommendations from the hospitals

Graduates of foreign medical schools before Jan 1 1940 whose schools were known to have had acceptable standards at the time of graduation may be considered if credentials and professional experience in the United States are acceptable to the board Ability to write and speak English clearly is a primary requisite

Massachusetts Graduates of foreign medical schools who matriculated in medical school prior to Jan 1 1941 are eligible to apply for admission to the examinations Graduates of unapproved foreign medical schools who matriculated in medical school on or after Jan 1 1941 may apply to a Committee to review their qualifications

New Hampshire Diplomates of National Board of Medical Examiners eligible on reciprocity basis Temporary license valid until citizenship is leted may be given Considered on an individual basis

Michigan Completion of senior year in approved medical school in the United States or Canada or M S degree in any field allied with medicine from a graduate school affiliated with an approved medical school or in lieu of above certificate of an oral comprehensive examination in the basic sciences and clinical medicine by a joint screening board of examiners from the faculties of the medical schools of the University of Michigan and Wayne University

Minnesota Two year internship in Minnesota required Credentials must be submitted in original form and accompanied by notarized photostatic copies translated and will be verified and documents should bear evidence of being visaed by the U S Consul in the country wherein the *school is located*

New Jersey Original certificate covering medical courses original diploma and license in foreign country with translation by the Lawyers and Merchants Translation Bureau 11 Broadway New York City

North Dakota Applicant must take examination at University of North Dakota in conversational English and the basic medical sciences as required of second year medical students Temporary license issued which becomes permanent after six years of practice and after obtaining American citizenship

Rhode Island Must pursue postgraduate study or serve additional one year internship or residency After Jan 14 1955 must serve approved rotating internship in Rhode Island Applicant must be licensed to practice medicine and surgery in country in which school of graduation is *located*

South Dakota Applicant required to practice in an emergency area for four years under a temporary license and reappear before the board for permanent licensure After July 1 1955 only those cleared through IRO will *be eligible*

Vermont Must be diplomate of National Board of Medical Examiners

Virginia Applicant must be licensed to practice medicine and surgery in country in which school of graduation is located or must have completed the course of study and passed examinations equivalent to those required for a diploma or license conferring such full right to practice

New Jersey Internship completed in foreign countries after July 1 1934 not acceptable Acceptance limited to schools recognized by the board Considered on an individual basis After Jan 1 1955 must have minimum of three years training in a hospital approved by the board

New York Considered on an individual basis

North Carolina Considered on an individual basis

Ohio Graduates of schools of Continental Europe after 1943 are eligible if on accepted list If not licensed in a foreign country must have one year in hospital in the United States if not on accepted list two years of training in an approved hospital in the United States Considered on an individual basis

Pennsylvania Medical schools in China and Japan not acceptable

Rhode Island Matriculants in foreign medical faculties subsequent to Jan 1 1949 not acceptable unless applicant was a legal resident of Rhode Island at the time of matriculation at a foreign medical school and obtained his preprofessional training in the United States or Canada

Texas European graduates after 1939 limited to English speaking schools

Virginia Graduates of medical schools on accepted list admitted on same basis as approved medical schools in the United States and Canada Graduates of other foreign schools having the required length of study and diploma required for practice in the country of their graduation two years of internship in approved hospital in the United States or Canada within the past five years prior to application or one year of study in an approved medical school in lieu of one year of the internship may be considered for examination Noncitizens must sign declaration of intention to become a citizen

Hawaii Diplomates of National Board eligible on reciprocity basis

West Virginia Applicant must be resident of the state for three years preceding an application and be recommended by local medical society

Wisconsin 1953 Legislature established One Year Temporary Educational Permit which authorizes graduates of unapproved foreign schools to obtain residency training in approved hospitals May be renewed for two additional years

Virgin Islands Residence of six month required ranges from $1 to $10 Six states have a nonresident fee Guam does not charge a fee In Florida physicians are required to register with the state board of health, while Missouri, New York and West Virginia require biennial registration

Educational Council for Foreign Medical Graduates

When the program proposed by the Cooperating Committee on Graduates of Foreign Medical Schools was approved last year[2] by the organizations concerned, it was hoped that needed financing and staff would be obtained promptly so the program could be implemented at the earliest possible date Unfortunately, unforeseen difficulties were encountered in procuring a tentative declaration of tax exemption under the proper section of the Bureau of Internal Revenue's code These difficulties have been overcome just recently

The Educational Council has made formal application to one of the large philanthropic foundations for funds to match the generous commitment previously made by the Kellogg Foundation The new application was approved just as this material was going to press The administrative staff for the Educational Council now will be recruited promptly and detailed, with final planning being undertaken with anticipation that the program will become effective by late 1957 or early 1958

The board of the Educational Council has vigorously pursued its duties under the leadership of Dr Murray Kinsman as chairman, Dr Edwin Hamilton as vice chairman, and Dr Sarah Hardwicke as treasurer It is their intention to keep all interested fully informed in regard to further significant developments through published statements in THE JOURNAL

Licensure of Foreign Trained Physicians

In 1950, the Council on Medical Education and Hospitals of the American Medical Association and the Executive Council of the Association of American Medical Colleges developed a list of foreign medical schools whose graduates they recommend for consideration on the same basis as graduates of approved medical schools in the United States The list was offered as an advisory grouping for the use of any agency or organization that might find it helpful The position of the councils with respect to schools not named in the list is that they neither approve nor disapprove such schools The credentials of graduates of schools not included in this listing must be evaluated by those other agencies, licensing boards, organizations, or institutions to whom graduates of the schools apply for recognition When the Educational Council for Foreign Medical Graduates becomes active and its proposal for the evaluation service for foreign medical graduates is put into effect, the listing of foreign medical schools will have no further value and will be discontinued

The present requirements for foreign-trained physicians seeking medical licensure in the United States and its territories and outlying possessions are given in table 27 Foreign-trained physicians are not eligible for licensure in 10 states, the Canal Zone, and Puerto Rico Twenty-one boards limit licensure to those who have graduated from schools in the approved listing Other boards find the list useful in the evaluation of credentials while some boards maintain their own list of schools whose graduates are acceptable for licensure Seven boards do not require citizenship, 15 boards require declaration of intention, and 21 boards require full citizenship Twenty-eight boards reported that the foreign-trained physician must serve an internship or obtain further medical training in the United States In addition to the items tabulated in this table, 19 boards have other specific requirements for foreign-trained physicians and 15 boards reported varying exemptions The factual data pertaining to these regulations are included in the text immediately below the table

This chart was developed by the Council on Medical Education and Hospitals of the American Medical Association in an effort to assist the foreign-trained physician seeking licensure in the United States While an attempt has been made to present the situation as it exists, the table is intended to give only a summary of existing requirements Persons interested in licensure should supplement these data by communicating with the licensing boards Medical licensure in the United States is a 'state right' and is entirely under the jurisdiction of the governments of the individual states The power to license physicians is exercised through the medical licensing board of each state Official supplementary information concerning the acceptability of foreign credentials should be obtained directly from the licensing boards

The Council also publishes a compendium of information concerning foreign medical schools and the status of foreign medical credentials in the United States that has been prepared as an aid to foreign-trained physicians In addition to data pertaining to medical licensure, this booklet contains sections pertaining to graduate training in the medical specialties undergraduate medical study in the United States, advanced standing in American medical schools, and medical study in foreign medical schools

Table 28 records the number of graduates of foreign faculties of medicine examined for medical licensure by 37 boards in 1956 The figures include both American and foreign-born physicians educated abroad Graduates of medical schools in the Philippines, New Zealand, 16 South and Central American countries, 24 countries in Europe, and 13 countries in Asia were represented at examinations The number totaled 1,783 Graduates of 213 medical schools and five licensing corporations were examined The number who

were successful was 1,012, failures numbered 771, or 43.2%. More than 50 graduates each from the universities of Havana, Munich, Bologna, and Mexico City were tested in 1956, and more than 20 graduates each from 17 other schools were examined.

The greatest number examined by any one state was 467 in New York, of whom 193 passed and 274, or 58.7%, failed. Illinois examined 261, of whom 79 passed and 182, or 69.7%, failed. There were 177 examined in California, of whom 129 passed and 48, or 27.1% failed, 166 in Ohio, of whom 117 passed and 49, or 29.5%, failed, 115 in Virginia, of whom 84 passed and 31, or 27%, failed, and 106 in Maryland, of whom 71 passed and 35, or 33%, failed. Other states examined fewer than 100 each.

Table 29 presents the number of graduates of foreign faculties of medicine examined for medical licensure in the United States in 27 years (1930-1956). In 1936 the number of foreign-trained physicians seeking licensure in the United States began to increase, and by 1940 over three times as many were tested as in

1936 Beginning in 1944, the numbers examined decreased until 1951, when there was a noticeable increase In each succeeding year the numbers examined has increased There was a slight increase in 1956 over the previous year in the numbers examined, while the figure representing those who passed the examination in 1956 decreased as compared with 1955 At no time in the 27-year period did fewer than 30 7% fail in a given year The percentage of failures in 1956 was 43 2 and for the entire period shown the overall percentage of failures was 47 6

In table 30 figures are given for an 11-year period (1946-1956) showing the number of foreign-trained physicians licensed by each state board, both after written examinations and by endorsement of credentials To conserve space, in the first column under the headings "Examination' and "Reciprocity and Endorsement," the figures combine the years 1946 to 1951 inclusive Thereafter, they are given for each year While table 29 reflects the numbers of candidates registered after examination only and indicates the percentage failing in each year table 30 reflects the total licensed in each state In this 11-year period,

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Basic science laws currently exist in 19 states, the District of Columbia, and Alaska These laws provide for the establishment of a board of examiners in the basic sciences whose function is to determine the adequacy of background knowledge of the basic sciences of all candidates seeking licensure to practice in any of the healing arts recognized in the statutes The basic science boards have no licensing power, but a certificate indicating successful completion of their examinations is a prerequisite for licensure wherever such boards exist Table 33 lists the states, district, and territory where basic science laws exist and the year of their enactment There has been no legislation enacting basic science laws since 1951

TABLE 35 –*Reciprocity, Endorsement, Waiver, or Exemption Policies of Basic Science Boards*

Credentials Accepted

Alaska

Physicians are accepted on reciprocity from those states with which the board of medical examiners has established reciprocal agreements

Arizona

Any basic science certificate that has been obtained by an examination before the issuing board and provided that at least four subjects were passed at one sitting Practitioners licensed in a state requiring a basic science certificate prior to the passage of basic science legislation are eligible on a previous licensure basis

Arkansas

Reciprocity on the basis of written examination taken before all states except Florida and Iowa Credential of the National Board of Medical Examiners acceptable for reciprocal registration

Colorado

Reciprocity as to examination with the following basic science boards Alaska Arizona Arkansas Michigan Minnesota Nebraska Nevada New Mexico Oklahoma Oregon Rhode Island South Dakota Tennessee Texas and Washington

Reciprocity as to examination with the Iowa Basic Science Board is granted to those candidates having made original application to that board on or before June 1 1949 Candidates making application after that date and holding a certificate must meet the minimum requirements of the board, i e that the candidate pass an examination in the basic sciences under a basic science board and that he pass at one sitting at least four of the five subjects given by the Colorado board with subsequent passing of the fifth subject

With Connecticut and Wisconsin there is reciprocity as to examination in the subjects of anatomy physiology, and pathology Candidates from these states are required to pass the examinations in chemistry and bacteriology under this board

TABLE 35 —*Reciprocity, Endorsement, Waiver, or Exemption Policies of Basic Science Boards—Continued*

Credentials Accepted—Continued

Connecticut
No reciprocity Endorsement of the certificate of the National Board of Medical Examiners and of state licenses of graduates of American medical schools

District of Columbia
Reciprocity has not been established The board may exempt an applicant All applications are considered on an individual basis

Florida
No reciprocity waiver or exemption policies

Iowa
On an individual basis applications for registration by exemption are considered on the basis of a license from a board of medical examiners the certificate of a basic science board and the certificate of the National Board of Medical Examiners

Michigan
Certificates issued by examination are accepted for registration by waiver from the basic science boards of Alaska Arkansas Colorado District of Columbia Minnesota Nebraska New Mexico Rhode Island South Dakota Tennessee Texas Oklahoma Nevada Iowa Oregon Washington and Wisconsin
Applicants who present certificate from the basic science boards of Washington and Oregon are examined in bacteriology
Applicants who present certificates from the Wisconsin Basic Science Board are examined in bacteriology and chemistry
The Michigan board may accept in lieu of its own examination the basic science portion of the examination given by any legally constituted examining or licensing board in the healing arts if such examination is equal or equivalent to the examination given by the Michigan Board

Minnesota
Reciprocity on an automatic basis with the basic science boards of Arkansas Colorado Nebraska Oregon and Tennessee (after Feb 9 1950) and the part 1 examination of the National Board of Medical Examiners
Reciprocity on an individual basis with the basic science boards of Alaska Arizona Connecticut Michigan Nevada New Mexico Oklahoma South Dakota and Texas
Reciprocity on an individual basis with the medical licensing boards of Indiana Kansas Kentucky New York (subsequent to 1925) Oklahoma Texas Vermont Virginia and Washington
Partial credit granted for grades in certain subjects passed in examinations of medical licensing boards of Alabama Georgia Louisiana New York (subsequent to 1925) North Carolina Wisconsin and the District of Columbia

ebraska
No reciprocal agreements exist Waiver may be granted when certain requirements specified in the law have been met These requirements relate to age of the applicant moral character high school graduation or equivalent the fact of having passed an examination given by a basic science board or a licensing board in another state the requirements of which are not less than those of Nebraska and providing the other state concerned extends like privileges to those taking the examination in Nebraska States eligible for consideration are those states granting exemptions from examinations to those from Nebraska where the conditions of the laws and regulations have been met even though these conditions differ somewhat from the requirements of Nebraska States not eligible for such consideration are those states prohibited by law from granting waiver or reciprocity

evada
Reciprocity with basic science boards of Arizona Colorado Iowa Minnesota New Mexico Oklahoma Oregon South Dakota Tennessee Texas and Washington Waiver with basic science boards of Arkansas Florida Michigan Nebraska and Wisconsin (partial waiver)

ew Mexico
Reciprocity with basic science boards of Arizona Arkansas Colorado Iowa, Michigan Minnesota New Mexico Oklahoma Oregon South Dakota Tennessee Washington and Wisconsin Waiver granted to doctors who have been in continuous practice for 30 years or more

klahoma
Applicants are reviewed on an individual basis A basic science certificate is not a prerequisite for licensure by reciprocity but is a requirement for licensure by examination

Oregon
Reciprocity on the basis of written examination with basic science boards of Arkansas Colorado Iowa Minnesota Nebraska Nevada New Mexico Oklahoma South Dakota Tennessee Texas Washington and Wisconsin

Rhode Island
Endorsement after oral examination with Massachusetts Board of Registration in Medicine and basic science boards of Colorado District of Columbia and Oklahoma

South Dakota
Reciprocity with basic science boards of Arizona Arkansas Colorado Iowa Michigan Minnesota Nebraska Nevada New Mexico Oklahoma Oregon Tennessee Texas Washington and Wisconsin

Tennessee
Reciprocity with basic science boards of Alaska Arizona Arkansas Colorado District of Columbia Michigan Minnesota Nebraska Nevada New Mexico Oklahoma Oregon South Dakota Texas *Washington and Wisconsin*

Texas
Reciprocity with the basic science boards of Alaska Arizona Arkansas Colorado Iowa Michigan Minnesota Nebraska Nevada Oklahoma Oregon South Dakota Tennessee Washington and partial reciprocity with Wisconsin

Washington
Reciprocity on the basis of written examination with all states *having basic science boards Examination required in subjects* not covered in Washington examination

Wisconsin
Waiver to commissioned officers of the armed forces or the Public Health Service to an applicant who has passed part 1 of the examination of the National Board of Medical Examiners to a physician licensed to practice medicine in a state not having a basic science law or licensed in a state before the establishment of a basic science board provided he has served an internship or has practiced for at least one year since the license was granted to a physician licensed in Canada and to foreign trained physicians holding an M D degree from an acceptable school who are licensed to practice medicine in the country in which the school attended is located
Reciprocity on the basis of written examination with all states *having basic science boards*

certification by one of these methods are outlined in table 35

The results of examinations given and the number of certificates issued on the basis of waiver, exemption, reciprocity, or endorsement as reported by the basic science boards during 1956 are shown in tables 36 and 37 The laws do not specify that a candidate reveal his school of practice The basic science boards were developed for the purpose of insuring, insofar as possible, that all individuals who enter into the area of the healing arts have what is generally considered to be an adequate preparatory background Table 36 records the total number of candidates reported by the several boards as having been examined and the number who passed and failed No attempt has been made to differentiate the schools of the healing arts represented by the candidates examined or certified Seven states either had no failures or did not report

TABLE 35 —*Reciprocity, Endorsement, Waiver, or Exemption Policies of Basic Science Boards*

Credentials Accepted

Alaska

Physicians are accepted on reciprocity from those states with which the board of medical examiners has established reciprocal agreements

Arizona

Any basic science certificate that has been obtained by an examination before the issuing board and provided that at least four subjects were passed at one sitting Practitioners licensed in a state requiring a basic science certificate prior to the passage of basic science legislation are eligible on a previous licensure basis

Arkansas

Reciprocity on the basis of written examination taken before all states except Florida and Iowa Credential of the National Board of Medical Examiners acceptable for reciprocal registration

Colorado

Reciprocity as to examination with the following basic science boards Alaska Arizona Arkansas Michigan Minnesota Nebraska Nevada New Mexico, Oklahoma Oregon, Rhode Island South Dakota Tennessee Texas and Washington

Reciprocity as to examination with the Iowa Basic Science Board is granted to those candidates having made original application to that board on or before June 1 1949 Candidates making application after that date and holding a certificate must meet the minimum requirements of the board i e that the candidate pass an examination in the basic sciences under a basic science board and that he pass at one sitting at least four of the five subjects given by the Colorado board, with subsequent passing of the fifth subject

With Connecticut and Wisconsin there is reciprocity as to examination in the subjects of anatomy physiology and pathology Candidates from these states are required to pass the examinations in chemistry and bacteriology under this board

TABLE 35 —*Reciprocity, Endorsement, Waiver, or Exemption Policies of Basic Science Boards—Continued*

Credentials Accepted—Continued

Connecticut
No reciprocity Endorsement of the certificate of the National Board of Medical Examiners and of state licenses of graduates of American medical schools

District of Columbia
Reciprocity has not been established The board may exempt an applicant All applications are considered on an individual basis

Florida
No reciprocity waiver or exemption policie

Iowa
On an individual basis applications for registration by exemption are considered on the basis of a license from a board of medical examiners the certificate of a basic science board and the certificate of the National Board of Medical Examiners

Michigan
Certificates issued by examination are accepted for registration by waiver from the basic science boards of Alaska Arkansas Colorado District of Columbia Minnesota Nebraska New Mexico Rhode Island, South Dakota Tennessee Texas Oklahoma Nevada Iowa Oregon, Washington and Wisconsin
Applicants who present certificates from the basic science boards of Washington and Oregon are examined in bacteriology
Applicants who present certificates from the Wisconsin Basic Science Board are examined in bacteriology and chemistry
The Michigan board may accept in lieu of its own examination the basic science portion of the examination given by any legally constituted examining or licensing board in the healing arts if such examination is equal or equivalent to the examination given by the Michigan Board

Minnesota
Reciprocity on an automatic basis with the basic science boards of Arkansas Colorado Nebraska Oregon and Tennessee (after Feb 9 1950) and the part 1 examination of the National Board of Medical Examiners
Reciprocity on an individual basis with the basic science boards of Alaska Arizona Connecticut Michigan Nevada New Mexico Oklahoma South Dakota and Texas
Reciprocity on an individual basis with the medical licensing boards of Indiana, Kansas Kentucky New York (subsequent to 1925) Oklahoma Texas Vermont Virginia and Washington
Partial credit granted for grades in certain subjects passed in examinations of medical licensing boards of Alabama Georgia Louisiana, New York (subsequent to 1925) North Carolina Wisconsin and the District of Columbia

Nebraska
No reciprocal agreements exist Waiver may be granted when certain requirements specified in the law have been met These requirements relate to age of the applicant moral character high school graduation or equivalent the fact of having passed an examination given by a basic science board or a licensing board in another state the requirements of which are not less than those of Nebraska and providing the other state concerned extends like privileges to those taking the examination in Nebraska States eligible for consideration are those states granting exemptions from examinations to those from Nebraska where the conditions of the laws and regulations have been met even though these conditions differ somewhat from the requirements of Nebraska States not eligible for such consideration are those states prohibited by law from granting waiver or reciprocity

Nevada
Reciprocity with basic science boards of Arizona Colorado Iowa Minnesota, New Mexico Oklahoma Oregon South Dakota Tennessee Texas and Washington Waiver with basic science boards of Arkansas Florida Michigan Nebraska and Wisconsin (partial waiver)

New Mexico
Reciprocity with basic science boards of Arizona Arkansas Colorado Iowa Michigan Minnesota New Mexico Oklahoma Oregon South Dakota Tennessee Washington and Wisconsin Waiver granted to doctors who have been in continuous practice for 30 years or more

Oklahoma
Applicants are reviewed on an individual basis A basic science certificate is not a prerequisite for licensure by reciprocity but is a requirement for licensure by examination

Oregon
Reciprocity on the basis of written examination with basic science boards of Arkansas Colorado Iowa Minnesota Nebraska Nevada New Mexico Oklahoma South Dakota Tennessee Texas Washington and Wisconsin

Rhode Island
Endorsement after oral examination with Massachusetts Board of Registration in Medicine and basic science boards of Colorado District of Columbia and Oklahoma

South Dakota
Reciprocity with basic science boards of Arizona Arkansas Colorado Iowa Michigan Minnesota Nebraska Nevada New Mexico Oklahoma Oregon Tennessee Texas Washington and Wisconsin

Tennessee
Reciprocity with basic science boards of Alaska Arizona Arkansas Colorado District of Columbia Michigan Minnesota Nebraska Nevada New Mexico Oklahoma Oregon South Dakota Texas Washington and Wisconsin

Texas
Reciprocity with the basic science boards of Alaska Arizona Arkansas Colorado Iowa Michigan Minnesota Nebraska Nevada Oklahoma Oregon South Dakota Tennessee Washington and partial reciprocity with Wisconsin

Washington
Reciprocity on the basis of written examination with all states having basic science boards Examination required in subjects not covered in Washington examination

Wisconsin
Waiver to commissioned officers of the armed forces or the Public Health Service to an applicant who has passed part 1 of the examination of the National Board of Medical Examiners to a physician licensed to practice medicine in a state not having a basic science law or licensed in a state before the establishment of a basic science board provided he has served an internship or has practiced for at least one year since the license was granted to a *physician licensed in Canada* and to *foreign trained physicians* holding an M D degree from an acceptable school who are licensed to practice medicine in the country in which the school attended is located
Reciprocity on the basis of written examination with all states having basic science boards

certification by one of these methods are outlined in table 35

The results of examinations given and the number of certificates issued on the basis of waiver, exemption, reciprocity or endorsement as reported by the basic science boards during 1956 are shown in tables 36 and 37 The laws do not specify that a candidate reveal his school of practice The basic science boards were developed for the purpose of insuring, insofar as possible, that all individuals who enter into the area of the healing arts have what is generally considered to be an adequate preparatory background Table 36 records the total number of candidates reported by the several boards as having been examined and the number who passed and failed No attempt has been made to differentiate the schools of the healing arts represented by the candidates examined or certified Seven states either had no failures or did not report

Totals		58 666	14 291	19 5	26 027	84 693

certified fewer than 500

In 30 years (table 38) 84,693 certificates in the basic sciences have been issued, 58,666 by examination and 26,027 by reciprocity, endorsement, exemption, or waiver The percentage of failures in this period was 19 5

The fees for certification in the basic sciences in the states requiring such certification are given in table 39 Examination and endorsement meetings are held in most instances semiannually, although some boards meet quarterly THE JOURNAL publishes semimonthly the future dates of examination and reciprocity meetings of all basic science boards

In 1956 there were 4,475 examinations given by basic science boards, 3,734 were successful and 741 examination results were reported as unsuccessful, thereby failing to give evidence of basic preparation adequate to qualify for further consideration for licensure Figures on how many individuals these 741 examination failures represent were not available for this report The several basic science boards differ widely from each other in the restrictions put upon the candidate with respect to repetition of examinations that have been failed and the accumulation of credit For example, an applicant in one state must pass at least four of the six required sections at one examination session If he does not pass at least four of them, he must then be reexamined in all six subjects when he again applies A poorly prepared applicant may continue to reapply and be reexamined at subsequent examinations Thus, one person could conceivably be reported as a failure on four different examinations during a calendar year In another state, which does not have such a limitation in its law, credit can be accumulated from one examination to the next The variances which exist in the evaluation methods of the states makes it impossible to analyze the figures on a comparable basis from state to state

NATIONAL BOARD OF MEDICAL EXAMINERS

The National Board of Medical Examiners is a voluntary and unofficial examining agency, the purpose of which is to prepare and to administer qualifying examinations of such merit that legal agencies governing the practice of medicine within each state may in their discretion grant successful candidates a license without further examination

It is the function of the individual state medical licensing boards to determine who shall practice within their borders and to maintain high standards of medical practice in accordance with their own rules and regulations In recognition of the thoroughness and widely accepted standards of the National Board examinations its certificate is accepted as an adequate qualification by the medical licensing authorities of the states, the District of Columbia, and the territories with the following exceptions Arkansas, Florida, Georgia, Indiana, Louisiana, Michigan, North Carolina, and Texas The Georgia licensing board will accept certificates issued prior to October, 1953 The Michigan licensing board will accept applicants who have completed parts 1 and 2 prior to Nov 1, 1954, but requires a special written supplemental examination Supplemental oral examinations are required by the licensing boards of Illinois, Rhode Island, and Wyoming

The following boards of examiners of the basic sciences accept the examinations of the National Board in lieu of their own Alaska, Arkansas, Connecticut, Iowa, Minnesota, Nebraska, Tennessee, Wisconsin, and the District of Columbia Diplomates of the National Board are required to take an examination in the basic sciences before obtaining a medical license in Arizona, Colorado, Florida, Michigan, Nevada, New Mexico, Oklahoma, Oregon, Rhode Island, South Dakota, Texas, and Washington

The examinations leading to certification by the National Board are divided into three separate parts Parts 1 and 2, which are of the multiple choice type, may be taken by students during the course of their training in the medical school Each of the six examinations of part 1 and each of the five examinations of part 2 is developed by a separate committee which is appointed by the Board and which is composed of teachers and clinicians prominent in their own fields Whereas formerly the Educational Testing Service of Princeton N J helped in the development and analysis of the examinations of parts 1 and 2, all work pertaining to all aspects of the testing program, including scoring and statistical analysis is now carried on in the offices of the National Board The third, or final, part of the examination provides a total of seven hours for each candidate to demonstrate his ability to apply his knowledge of clinical problems in four major elements of general practice In each of these subjects

Totals	39 752	38 115	79	1 558	3 9

Examinations in part 1 were held during 1956 in June and September, and in part 2 in April and June Part 3 of the examination is administered through subsidiary boards located in the major cities of the United States during the last two weeks of June of each year Where indicated, interim part 3 examinations will be organized by an individual subsidiary board during the course of the year The dates of all examinations are posted on medical school bulletin boards and published in THE JOURNAL and in The National Board Examiner, the official publication of the National Board of Medical Examiners

The National Board admits to its examination any student in good standing in approved medical schools in the United States and Canada The National Board does not, at the present time, admit to its examinations graduates of other medical schools Upon receipt of a request initiated by a state licensing board, a specialty board, or a medical school, an individual trained in a foreign medical school may be admitted to the National Board examinations in order to satisfy special requirements or regulations of the licensing board, specialty board, or the medical school He is not considered a candidate for a certificate but is admitted to the examination as a service to the agency requesting the service and the grades are sent only to the board or school concerned

The tables that are presented refer to the results of examinations in all three parts since 1922, including the number who passed and failed examinations and the number certified This is the 35th annual compilation of these statistics The board s first examination was given in October, 1916 From that date and up to and including a test given in June, 1921, 11 examinations were given and 268 candidates were certified Since 1922 the examination has been divided into three parts, which must be taken and completed in the following sequence part 1, a written examination in six basic science subjects, part 2, a written examination in five major clinical divisions and their component subjects or subdivisions, and part 3, a clinical and practical evaluation of the candidate s ability in observation, in diagnostic acumen, and in the principles of therapy, applicable to the four major elements of general practice, namely, clinical medicine, pediatrics, clinical surgery, and obstetrics and gynecology

Tables 40 and 41 record the results of examinations given in parts 1 and 2 during 1956 and for each year since 1922 The data shown in these tables represent examinations conducted rather than persons examined, and the figures thus include candidates who fail and are reexamined during the same year and those who may pass parts 1 and 2 in the same year

There were 3,475 examinations in part 1 given in 1956, 2,675 passed, and 290, or 10 8%, failed Incomplete examinations numbered 510 In part 2, 2,182 examinations were held, 2,153 passed, and 26, or 1 2% failed Three incomplete examinations were given

From 1922 to 1956, inclusive, a total of 74,699 examinations have been given in part 1 and 39,752 in part 2 The successful examinations totaled 45,892 in part 1 and 38,115 in part 2 In the 35-year period shown, there have been 7,117 failures in part 1 (13 7%) and 1,558 (3 9%) in part 2

In 1956, 2,085 tests were given in part 3, 2,072 passed, and 13 (0 6%) failed Results of examinations in part 3 in 1956 and in the 34 preceding years are given in table 42 In 35 years, 34,653 were tested, of whom 33 827 were granted the certificate of the board The percentage of failures in the board's final examination for the 35-year period was 2 3

The 2,072 physicians certified as diplomates in 1956 represented 64 medical schools in the United States and Puerto Rico, 9 in Canada, and 11 in other countries The school and the number of examinees from each are included in table 43

A number of medical schools use National Board examinations for their own purposes In some schools the entire second year class takes part 1 at the end of the second year, in others part 2 serves as a comprehensive examination at the end of the fourth year, in still other schools both parts 1 and 2 are taken by all students At the present time there are 35 medical schools in which 25 or more students take National Board examinations In 23 schools, the National Board examinations are required for the entire class for either part 1 or part 2, or both parts 1 and 2

The officers of the board are Walter A Bloedorn, M D , President, Creighton Barker, M D , Vice-President, John P Hubbard, M D , Executive Secretary and Treasurer, William V Clemans, Ph D , Director of Testing Services, Christian J Lambertsen, M D , Assistant Secretary, George D Ludwig, M D , Assistant Secretary, J S Rodman, M D , Honorary Medical Secretary, and Everett S Elwood, Consultant on State Board Relations

The address of the board is 133 S 36th St , Philadelphia 4

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

During the month of March I had the distinct good fortune to inspect medical installations of the U S armed forces in the Pacific area and to visit several medical schools and medical associations in the Far East It also was my pleasure to have Dr Leo Bartemeier, Chairman of the A M A 's Council on Mental Health, Rear Adm Thomas G Hays, M C, U S Navy, and Commander E W White, U S Navy, as my travel companions and advisers

My first-hand survey of the Navy medical facilities, as well as the Army and Air Force installations, convinced me that the health and welfare of our armed forces personnel are being handled carefully and expertly by the medical personnel assigned to that all-important task Specifically, (1) emergency medical facilities are excellent, and they are available almost immediately to the sick or injured, (2) good hospital care is an hour or less away for almost every man and woman serving in the Pacific area, and (3) expert medical care and the finest hospitalization in extreme and very serious cases are only a few hours away

In addition to the availability of facilities and medical personnel, I found the armed forces' physicians just as dedicated as civilian doctors in the United States In fact, I found that the service physician was ready and willing to meet almost any challenge and to render the best possible care even if facilities or equipment are not always readily available Indeed, I would regard the morale and dedication of the medical officers, nurses, and enlisted personnel as the finest I have seen anywhere

To parents, wives, relatives, and friends of members of the armed forces in the Pacific, I say You do not have to worry about medical care—quantity or quality—for servicemen It is the best possible, and all the needs of every serviceman can, and will, be met

I also am happy to report that medical personnel is trying to assist local populations in the care of their sick and injured, whenever and wherever possible I have seen this assistance being rendered fully and capably at hospitals and outpatient clinics Personally, I feel that our armed forces—particularly the medical personnel—have a great opportunity to promote good will and friendship between the people of the area and the people of the United States So it was gratifying to see so many service doctors spreading the humanitarianism so closely identified with the United States and the American medical profession

While I was on the Pacific inspection trip, I made approximately 20 talks to armed forces medical personnel, to students and faculty of medical schools, and to members of several medical associations The entire trip was a pleasant and enlightening experience, and the line officers were extremely helpful in providing us with comfortable, swift, and safe transportation A report of my findings is now in the hands of Adm B W Hogan, surgeon general of the U S Navy

As this is my last President's Page before the curtain falls on my term of office, I want to express my sincere appreciation to each and every member of the A M A for the confidence placed in me and for elevating me to medicine's highest office in the land

Whatever has been accomplished during my service to the A M A is the direct result of the efforts of hard-working physicians and staff personnel I claim no credit I merely am happy to have had the opportunity to work with so many capable persons everywhere in the country and to contribute my small portion to the betterment of the A M A and the medical profession

If I had to single out one principle that has guided me during my term, it would be Try to keep medicine as free and dedicated as you found it I hope every physician will remember this principle, and will make it his personal duty to carry on the heritage of medical freedom that is ours today Furthermore, it is the duty and responsibility of our profession to pass on to the younger and succeeding doctors the same privileges and opportunities to practice medicine that we have had Our freedom in exercising our best judgment and using our capabilities in the care of the sick must never be hindered or hampered The task of maintaining our traditions may not be easy, but it will be well worth the extra time we devote to this great cause

To all 160,000 A M A members, thank you for allowing me to serve the greatest medical organization in the world

DWIGHT H MURRAY, M D, Napa, Calif

ORGANIZATION SECTION

HEALTH IN SCHOOLS

How can educators cooperate to encourage widespread immunization against poliomyelitis? What is the viewpoint of representative physicians on competitive athletics in grade schools? How do the nation's no 1 teachers' and physicians' organizations feel about health education and physical education programs in all schools—from elementary grade level through college? These questions have been answered definitively and with official tone within the text of a dozen resolutions adopted recently by one of the oldest interprofessional organizations in America It has the long-breath title of Joint Committee on Health Problems in Education of the National Education Association and American Medical Association The group has been functioning continuously for 46 years—developing effective liaison, helping formulate policy, publishing appropriate materials, and serving as a board of review on matters related to health in our nation's schools

The five physician members, nominated by the A M A Board of Trustees, all have a keen interest in school problems The five N E A representatives, selected by their organization's president, are particularly concerned with the health of pupils One result of this intense dual approach is a combined and cohesive medical-educational view on school health matters At a meeting March 11, 12, and 13, the Joint Committee

—Planned to draw up a check list for local communities to evaluate their own school health programs

—Studied a progress report on a new volume, Healthful School Living"

—Discussed a report on dental health in schools with representatives of the American Dental Association

—Determined subcommittee progress on such topics as mental health in the classroom, health of school personnel, and health aspects of pupil transportation

(Reelected to a second term as Joint Committee chairman was Delbert Oberteuffer, Ph D , of the Ohio State University department of physical education A pediatrician from Fond du Lac, Wis, Dr E H Pawsat, was named vice-president, and Dr Donald A Dukelow, of the A M A headquarters staff, was elected secretary)

Publications and Resolutions

The fact that there is a keen interest among doctors and educators in all phases of school health is shown in the wide call for publications prepared by the Joint Committee "Healthful School Living," third of three basic books published in the past decade ("Health Education' and 'School Health Services' are the others), now rounds out all phases of the school health program Dozens of pamphlets have been published since 1920 by the Joint Committee—and republished as often as 10 times to meet the rising demand They have covered such varied subjects as school health policies, sex education, health appraisal, school lunch programs, sight and hearing conservation, the nurse in the school, classroom lighting, physical growth charts, fatigue, and sleep habits for children

Among the resolutions adopted at the March meeting were those

—Reemphasizing the need for adequate programs of health education and physical education in all schools

—Declaring that fitness covers all aspects of organic, psychological, and social growth—and is not "testable only by muscular strength, agility, or flexibility

—Sounding approval of an American Academy of Pediatrics report which recognizes the value of properly directed competitive sports for youth but condemns high pressure elements in athletics and body-contact sports (such as boxing and tackle football) for immature children

—'Strongly" urging that pupils at all grade levels be given Salk poliomyelitis vaccine, and that principals, teachers, and other school employees work with the medical profession to encourage broad community acceptance of this important preventive procedure '

—Urging widespread study and use of a newly rewritten yearbook entitled 'Fit to Teach" It now is in the final stages of preparation

—Commending the National Congress of Parents and Teachers for their promotion of a new program which tends to bring children and their parents into continual and personal contact with medical and dental resources of the community

Committees at Local Level

While physicians and educators in this national Joint Committee set the pace for better health in our schools, their actions alone do not form the driving force at classroom level Some 400 school health committees of county medical societies are at work day after day with teachers and principals across the land to lead the many health projects in communities

These activities range from medical examinations to health guidance in sports A statewide conference on physicians and schools in Connecticut brings together more than 200 doctors, public health officials, and educators Local medical societies sponsor similar joint sessions in Wisconsin and California And, in Montana, 11 cities take part in a "circuit' type of program featuring representatives of these professions as they cope with specific situations in each of the cities

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

During the month of March I had the distinct good fortune to inspect medical installations of the U. S. armed forces in the Pacific area and to visit several medical schools and medical associations in the Far East. It also was my pleasure to have Dr. Leo Bartemeier, Chairman of the A. M. A.'s Council on Mental Health, Rear Adm. Thomas G. Hays, M. C., U. S. Navy, and Commander E. W. White, U. S. Navy, as my travel companions and advisers.

My first-hand survey of the Navy medical facilities, as well as the Army and Air Force installations, convinced me that the health and welfare of our armed forces personnel are being handled carefully and expertly by the medical personnel assigned to that all-important task. Specifically, (1) emergency medical facilities are excellent, and they are available almost immediately to the sick or injured, (2) good hospital care is an hour or less away for almost every man and woman serving in the Pacific area, and (3) expert medical care and the finest hospitalization in extreme and very serious cases are only a few hours away.

In addition to the availability of facilities and medical personnel, I found the armed forces physicians just as dedicated as civilian doctors in the United States. In fact, I found that the service physician was ready and willing to meet almost any challenge and to render the best possible care even if facilities or equipment are not always readily available. Indeed, I would regard the morale and dedication of the medical officers, nurses and enlisted personnel as the finest I have seen anywhere.

To parents, wives, relatives, and friends of members of the armed forces in the Pacific, I say: You do not have to worry about medical care—quantity or quality—for servicemen. It is the best possible, and all the needs of every serviceman can, and will, be met.

I also am happy to report that medical personnel is trying to assist local populations in the care of their sick and injured, whenever and wherever possible. I have seen this assistance being rendered fully and capably at hospitals and outpatient clinics. Personally, I feel that our armed forces—particularly the medical personnel—have a great opportunity to promote good will and friendship between the people of the area and the people of the United States. So it was gratifying to see so many service doctors spreading the humanitarianism so closely identified with the United States and the American medical profession.

While I was on the Pacific inspection trip, I made approximately 20 talks to armed forces medical personnel, to students and faculty of medical schools, and to members of several medical associations. The entire trip was a pleasant and enlightening experience, and the line officers were extremely helpful in providing us with comfortable, swift, and safe transportation. A report of my findings is now in the hands of Adm. B. W. Hogan, surgeon general of the U. S. Navy.

As this is my last President's Page before the curtain falls on my term of office, I want to express my sincere appreciation to each and every member of the A. M. A. for the confidence placed in me and for elevating me to medicine's highest office in the land.

Whatever has been accomplished during my service to the A. M. A. is the direct result of the efforts of hard-working physicians and staff personnel. I claim no credit. I merely am happy to have had the opportunity to work with so many capable persons everywhere in the country and to contribute my small portion to the betterment of the A. M. A. and the medical profession.

If I had to single out one principle that has guided me during my term, it would be: Try to keep medicine as free and dedicated as you found it. I hope every physician will remember this principle, and will make it his personal duty to carry on the heritage of medical freedom that is ours today. Furthermore, it is the duty and responsibility of our profession to pass on to the younger and succeeding doctors the same privileges and opportunities to practice medicine that we have had. Our freedom in exercising our best judgment and using our capabilities in the care of the sick must never be hindered or hampered. The task of maintaining our traditions may not be easy, but it will be well worth the extra time we devote to this great cause.

To all 160,000 A. M. A. members, thank you for allowing me to serve the greatest medical organization in the world.

HEALTH IN SCHOOLS

How can educators cooperate to encourage widespread immunization against poliomyelitis? What is the viewpoint of representative physicians on competitive athletics in grade schools? How do the nation's no 1 teachers' and physicians' organizations feel about health education and physical education programs in all schools–from elementary grade level through college? These questions have been answered definitively and with official tone within the text of a dozen resolutions adopted recently by one of the oldest interprofessional organizations in America It has the long-breath title of Joint Committee on Health Problems in Education of the National Education Association and American Medical Association The group has been functioning continuously for 46 years—developing effective liaison, helping formulate policy, publishing appropriate materials, and serving as a board of review on matters related to health in our nation's schools

The five physician members, nominated by the A M A Board of Trustees, all have a keen interest in school problems The five N E A representatives, selected by their organization's president, are particularly concerned with the health of pupils One result of this intense dual approach is a combined and cohesive medical-educational view on school health matters At a meeting March 11, 12, and 13, the Joint Committee

–Planned to draw up a check list for local communities to evaluate their own school health programs

—Studied a progress report on a new volume, 'Healthful School Living'

—Discussed a report on dental health in schools with representatives of the American Dental Association

–Determined subcommittee progress on such topics as mental health in the classroom, health of school personnel, and health aspects of pupil transportation

(Reelected to a second term as Joint Committee chairman was Delbert Oberteuffer, Ph D , of the Ohio State University department of physical education A pediatrician from Fond du Lac, Wis, Dr E H Pawsat, was named vice-president, and Dr Donald A Dukelow, of the A M A headquarters staff, was elected secretary)

Publications and Resolutions

The fact that there is a keen interest among doctors and educators in all phases of school health is shown in the wide call for publications prepared by the Joint Committee "Healthful School Living," third of three basic books published in the past decade ('Health Education' and "School Health Services' are the others), now rounds out all phases of the school health program Dozens of pamphlets have been published since 1920 by the Joint Committee—and republished as often as 10 times to meet the rising demand They have covered such varied subjects as school health policies, sex education, health appraisal, school lunch programs, sight and hearing conservation, the nurse in the school, classroom lighting, physical growth charts, fatigue, and sleep habits for children

Among the resolutions adopted at the March meeting were those

–Reemphasizing the need for adequate programs of health education and physical education in all schools

–Declaring that fitness covers all aspects of organic, psychological, and social growth–and is not "testable only by muscular strength, agility, or flexibility"

–Sounding approval of an American Academy of Pediatrics report which recognizes the value of properly directed competitive sports for youth but condemns high pressure elements in athletics and body-contact sports (such as boxing and tackle football) for immature children

–"Strongly' urging that pupils at all grade levels be given Salk poliomyelitis vaccine, and that principals, teachers, and other school employees work with the medical profession to encourage broad community acceptance of this important preventive procedure'

–Urging widespread study and use of a newly rewritten yearbook entitled 'Fit to Teach" It now is in the final stages of preparation

–Commending the National Congress of Parents and Teachers for their promotion of a new program which tends to bring children and their parents into continual and personal contact with medical and dental resources of the community

Committees at Local Level

While physicians and educators in this national Joint Committee set the pace for better health in our schools, their actions alone do not form the driving force at classroom level Some 400 school health committees of county medical societies are at work day after day with teachers and principals across the land to lead the many health projects in communities

These activities range from medical examinations to health guidance in sports A statewide conference on physicians and schools in Connecticut brings together more than 200 doctors, public health officials, and educators Local medical societies sponsor similar joint sessions in Wisconsin and California And, in Montana, 11 cities take part in a 'circuit' type of program featuring representatives of these professions as they cope with specific situations in each of the cities

The A M A Bureau of Health Education says, "There is evidence of increased interest and participation by medical societies in joint activity toward program planning and policy making in school health, in cooperation with other professions concerned with the health problems of children of school age' But there is more than immediate health problems involved in this interprofessional accord Looming large is the broader concept of preventive health for years to come throughout the nation What better place is there than a school to appraise the health of groups of children on a continuing basis? What better place could show, by example and precept, how better health can mean better students and, ultimately, better citizens?

FEDERAL MEDICAL LEGISLATION

First Session, 85th Congress

National Library of Medicine

Representative Collier (R, Ill), in H R 2413, has introduced a bill which would create a National Library of Medicine to be located in Chicago Books, collections, records, and equipment from the Armed Forces Medical Library would be turned over to the new library The measure creating such a library, under the jurisdiction of the Public Health Service, became public law in August, 1956 Equipment, books, and collections from the Armed Forces Medical Library were transferred to it The site of the new library will be selected by the Board of Regents This bill was referred to the House Administration Committee

Federal Advisory Council of Health

Representative Frelinghuysen (R, N J), in H R 2435, would establish 'in the Executive Office of the President, a Federal Advisory Council of Health to be composed of four persons who are members of the medical profession and three persons with distinguished records in fields other than medicine, to be appointed by the President, and to hold office at his pleasure" The function of the council would be

First Make a continuous evaluation of and recommendations as to policies and programs relating to Federal medical care and national health

'Second Advise on measures to assure adequate health manpower and hospital facilities for the Nation s health

Third Review the various proposals and programs relating to hospital construction involving Federal funds, including Federal grants

Fourth Advise with respect to the coordination of regional hospital services of all departments and agencies in the executive branch of the Government

"Fifth Advise with respect to more systematic cross-servicing between the various Federal medical agencies

"Sixth Advise upon measures for the adequate training and selection of the medical staffs of all Federal services

"Seventh Advise the executive departments and agencies on all Federal medical policies and programs

"Eighth Advise the Selective Service System on the mobilization of medical personnel

"Ninth Advise concerning systems of project grants for health-research programs of the Federal Government

'Tenth Report periodically to the President and to the executive departments and agencies involved, on the success or failure of Federal health programs and policies

'Eleventh Report to the President and advise the Bureau of the Budget and the Congress with respect to such matters as they may request

"Twelfth Assist the Secretary of Defense to develop recommendations for revision of the Selective Service Act, as amended, so as to effect maximum utilization of medical personnel

Thirteenth Advise the Administrator of the Veterans Administration with respect to recommendations for closing certain hospitals belonging to such Administration

"Fourteenth Review the manner in which the hospital facilities of the Veterans' Administration are being used and make recommendations for the disposal of more economic utilization of such facilities

Fifteenth Advise the President, or any committee established or designated by him, with respect to the policies, programs, and operations of the Food and Drug Administration and the Agricultural Research Service in the Department of Agriculture, with a view to eliminating those which are no longer necessary under present conditions and eliminating conflicts and overlapping of jurisdiction and functions between departments

Sixteenth Make recommendations to improve preventive health services, including those rendered in connection with medical care of Federal beneficiaries, in the interests of both health conservation and long range economy

'Seventeenth Review and make recommendations to the President with respect to the health research programs of the Federal Government

'Eighteenth Examine the means of establishing cooperative planning among the Federal agencies which provide psychiatric care

'Nineteenth Service as consultant to the President s adviser on personnel with respect to making more uniform the personnel systems of the several Federal agencies using health personnel"

This measure was referred to the Committee on Interstate and Foreign Commerce

---

From the Washington Office of the American Medical Association

Registration and Reporting of Welfare and Pension Plans

A group of bills similar to each other have been introduced requiring the registration and reporting of receipts, income, disbursements, assets, liabilities, and financial activities of health, welfare, and pension plans The reports would be made public under regulations prescribed by the Secretary of Labor or the Federal Security and Exchange Commission The bills are H R 2437 and H R 6014, by Representative Frelinghuysen (R , N J), H R 4653, by Representative Green (D , Ore), H R 5994, by McConnell (R , Pa.), H R 6513, by Representative Ruess (D , Wis), S 1121, by Senator Douglas (D , Ill) for himself and Senators Murray (D , Mont) and Ives (R , N Y), and S 1145 by Senator Ives (R , N Y) for himself and Senators Allott (R , Colo) and Smith (R , N J) The House measures were referred to the Committee on Education and Labor The Senate bills were referred to the Committee on Labor and Public Welfare

Poliomyelitis Vaccine Assistance Act Amendment

Representative Bennett (D , Fla), in H R 2536, would authorize and direct the surgeon general to reallocate unused allotments of those states which do not utilize their share of the federal grants for Salk vaccine that expire June 30, 1957 He would also allow those eligible to include persons up to 40 years of age and pregnant women This measure was referred to the Interstate and Foreign Commerce Committee

Salk Vaccine Control by HEW

Representative Green (D , Ore), in H J Res 281, would authorize the Secretary of Health, Education, and Welfare to exercise control of the distribution, use, and selling price of poliomyelitis vaccine to Dec 31, 1957 This bill contains a statement that 'the demand for poliomyelitis vaccine far exceeds the supply" Control within each state would be placed in the state health department The vaccine purchased or contracted to be purchased by the National Foundation for Infantile Paralysis would not be subject to the provisions of this resolution as long as such supply was owned and distributed by the foundation This bill was referred to the Committee on Interstate and Foreign Commerce

Water Pollution Control

Representative Rogers (D , Colo) in H R 2834, and Senators Allott (R , Colo) and Carroll (D , Colo), in S 1262, have introduced identical measures that would amend the Water Pollution Control Act to remove the maximum dollar limitation on grants for construction of sewage treatment works It would, however, retain the 30% federal share limitation These measures were referred to the Committee on Public Works

Sanitation Facilities and Services for Indians

Representative Udall (D , Ariz), in H R 2894, and Senator Chavez (D , N Mex), in S 1498, have introduced measures identical to H R 246, by Representative Judd (R , Minn), previously reported, which would authorize the surgeon general of the Public Health Service, to conduct surveys, until June 30, 1961, as to the need for sanitary facilities and measures, and to develop projects for the construction of such facilities among the Indian population The Indian tribes would be encouraged to assume or share the responsibility for the construction and operation of the facilities The measures state, The Surgeon General shall consult with, and encourage the participation of, States and political sub-divisions thereof, and the government of the Territory of Alaska in carrying out the provisions of this Act' These measures were referred to the respective committees on Interior and Insular Affairs

Repeal of Alaska Mental Health Enabling Act

Representative O'Neill (D , Mass), at the request of a constituent, has introduced H R 3075, a measure which would repeal the Alaska Mental Health Enabling Act (Public Law 830 of the 84th Congress) This measure has been referred to the Committee on Interior and Insular Affairs

Medicare for Certain Retired Military Personnel

Representative Boggs (D , La), in H R 3208, and Senator Kefauver (D , Tenn), in S 1259, have introduced identical measures that would amend the Dependents Medical Care Act to entitle certain retired members of the uniformed services to the same benefits as dependents of the uniformed services The retired member would have to be 65 years of age or have over 20 years or more of active duty Under the present law, retired members of the armed forces may receive medical care in military facilities Under the proposed bills, they could receive care in civilian facilities also These bills have been referred to the respective Armed Services committees

U S Armed Forces Medical Academy

Senator Capehart (R , Ind), in S 596, has introduced a bill identical to H R 1055, by Representative Bennett (D , Fla), that would establish an Armed Forces Medical Academy, similar to the Army, Navy, and Air Force military academies These bills were referred to the Armed Services Committee

Child Health and Welfare Amendments of 1957

Representative Bennett (D , Fla), in H R 3359, would amend the child welfare provisions of the Social Security Act to authorize the earmarking of up to 12 5% the annual child health and welfare appropriations for special projects of regional or national significance Such project grants could be made not only to state agencies administering state plans but also to public and nonprofit institutions of higher education or research with the cooperation of the state agency At the present time grants are given to states only This was referred to the Ways and Means Committee

National Multiple Sclerosis Institute

Representative Hoeven (R, Iowa), in H R 3485, proposes to establish a National Multiple Sclerosis Institute in the United States Public Health Service The institute would "provide for research and investigation with respect to the cause, prevention, and treatment of multiple sclerosis and related neurological diseases There is no definition of the relationship of the present National Institute of Neurological Diseases and Blindness to the proposed Multiple Sclerosis Institute The National Institute of Neurological Diseases and Blindness at present performs all of the functions outlined in the proposed bill The bill was referred to the Committee on Interstate and Foreign Commerce

Industrial Safety

Senators Smith (R, N J), and Ives (R, N Y), in S 815, and Representative Frelinghuysen (R, N J), in H R 6045, have introduced identical bills that propose "to provide for assistance to States in their efforts to promote, establish, and maintain safe workplaces and practices in industry, thereby reducing human suffering and financial loss and increasing production through safeguarding available manpower

According to these bills the Secretary of Labor would administer allotments to states and the state labor agency would supervise the state safety plans The federal funds would be apportioned on a formula based on (1) the number of wage earners, (2) special hazards, (3) financial needs of respective states, and (4) such other factors as the Secretary finds relevant Payments to states for the first two years could not exceed 75% of the total expenditure, for the second two years, 66 6%, and, thereafter, not over 50% of the total expenditures under state plans The coal industry is covered by another provision and would not be included in this program There was no mention in the proposal of the state health agency or of physicians The Senate measure was referred to the Labor and Public Welfare Committee and the House measure to the Committee on Education and Labor

National Compulsory Health Insurance

Senator Murray (D, Mont), in S 844, and Representative Dingell (D, Mich), in H R 3764, have introduced identical measures that propose to establish a national program of compulsory health insurance It would be financed by a 3% tax on wages up to $6,000 annually plus up to 1% of wages from the U S Treasury The participants would be furnished medical and dental care and home nursing services up to 60 days, except for nervous or mental diseases or tuberculosis State agencies would make agreements with physicians, hospitals, and other providers of care to provide medical services, or the states could employ voluntary groups providing care or could utilize various health plans Payment could be made to physicians on a fee-for-services, per capita, or salary basis, or a combination of any two of these three methods In cases of hospitals, payment would be made on the basis of reasonable cost Providers of care could terminate an agreement after reasonable notice, could carry on their private practice, and would also have the right to accept or refuse patients

Five-tenths per cent of the cost of the total health program would be authorized for grants to public and nonprofit institutions or schools for training health personnel that are needed The Senate bill was referred to the Committee on Labor and Public Welfare and the House measure to the Committee on Interstate and Foreign Commerce

United States Nursing Academy

Senator Ives (R, N Y), in S J Res 30, proposes to establish a United States Academy of Nursing to furnish 'an adequate and continuous flow of young women trained in the profession of nursing and qualified to meet the needs of the armed services" The Secretary of Defense would select one "cadette' for each member of Congress from among nominees submitted by the member The President would appoint 30 cadettes' annually Graduates of the academy would be required to serve not less than three consecutive years in the armed forces This proposal was referred to the Committee on Armed Services

Tax Credit for Educational Expenses

Senator Humphrey (D, Minn), in S 868, and Representative Roosevelt (D, Calif), in H R 4597, would provide that in individual shall be allowed, as credit against his income tax, 30% of the aggregate amount paid during the taxable year to institutions of higher education as tuition or fees either for himself or any individual This allowance is against the income tax imposed and not against the net income upon which the income tax is based The Senate bill was referred to the Committee on Finance and the House measure to the Committee on Ways and Means

Representatives Perkins (D, Ky), in H R 5684, and Rhodes (D, Pa), in H R 4594, have introduced essentially identical measures Both measures were referred to the Committee on Ways and Means

Representative Jackson (R, Calif) has introduced a similar measure, H R 4396, with the exception that the tax credit "shall not exceed $450 on account of such cost of education paid by the taxpayer for the education of any one person, but the total credit allowed shall be the sum of the credits on account of the payments made by the taxpayer for the education of himself and for the education of other persons" This bill was referred to the Committee on Ways and Means

Tax Deduction for Educational Expenses

Representative Rodino (D, N J), in H R 4419, would allow a deduction from gross income in calculating income tax, for educational expenses incurred in the pursuit of education of a dependent at a college or university, including maintenance while pursuing such education This exemption would not be limited to the standard $600 per year exemption

Representative Fino (R, N Y), in H R 5469, would allow a deduction from the gross income for tuition paid for dependents at any level of education, elementary, secondary, or college

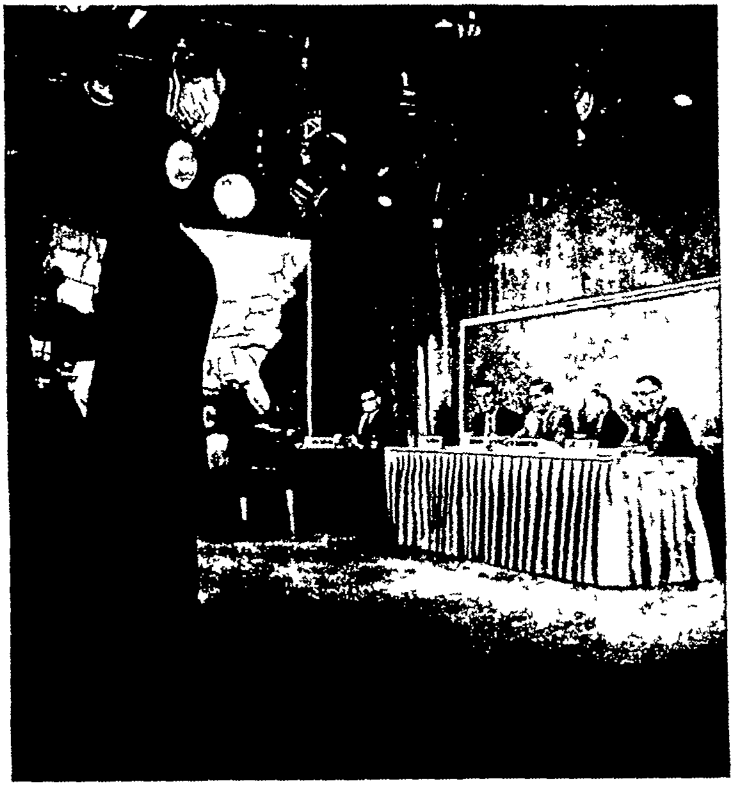
Representative Jennings (D, Va), in H R 5877, would allow the taxpayer an additional income tax exemption for a spouse or dependent who is a student The exemption would be valid when the taxpayer pays over half of the educational expenses incurred by such spouse or dependent during the calendar year in which the taxable year of the taxpayer begins These bills have been referred to the Ways and Means Committee

VIDEO LINKS FIVE MEDICAL MEETINGS

Some 2,000 physicians attending their annual medical association meetings in five states last month were linked as participants in a closed-circuit telecast exploring "The Physician and Emotional Disturbance" The hour-long postgraduate seminar on May 6 connected meetings in Florida, Kansas, Louisiana, Oklahoma, and North Carolina to five authorities on mental health in a Chicago television studio A moderator in each convention city was in two-way audio communication with panel members as they were viewed on separate 9-by-12 ft television screens Questions from the various meeting halls were heard in the studio and answered immediately

This "Videclinic" was presented by the Council on Mental Health of the American Medical Association and the five state societies, in cooperation with Smith, Kline & French Laboratories The program centered upon what the physician in general practice can do for the many patients who come to him with mild emotional disturbances or psychosomatic conditions Discussion was sparked by motion picture scenes of a patient describing his case to an inquiring family physician

Dr Leo H Bartemeier, Chairman of the A M A Council, was moderator of the panel Other panel members were Dr C Knight Aldrich, head of the University of Chicago, department of surgery, Dr E I Baumgartner, Secretary of the A M A Section on General Practice, Dr C H Hardin Branch, head of the University of Utah psychiatry department, and Dr Andrew S Tomb, chairman of the American Academy of General Practice liaison committee with the American Psychiatric Association



The Chicago "Videclinic" in action for five state medical association meetings last month (states shown on wall map) Moderator Dr Bartemeier is at left Other panelists are Drs Aldrich, Branch, Baumgartner, and Tomb Silhouetted at left is announcer

TRIP TO OIL REFINERY DISPENSARY

The medical department, Esso Standard Oil Company, will sponsor a field trip to the company's Bayway Refinery on one afternoon of the A M A meeting in New York In addition to a plant dispensary visit, a brief tour of refinery operations will be offered, emphasizing various aspects of environmental hygiene The number of visitors will be limited, and requests will be honored on a first-come, first-served basis Physicians who are interested are urged to communicate in advance with Leo Wade, Medical Director, Esso Standard Oil Company, 15 W 51 St, New York 19 Transportation will be provided

MEDICINE AND THE LAW

BLOOD TESTS FOR INTOXICATION UPHELD BY UNITED STATES SUPREME COURT

While driving a pickup truck on the highways of New Mexico, Paul H. Breithaupt, the petitioner, was involved in a collision with a passenger car. Three occupants of the car were killed, and he was seriously injured. A pint whiskey bottle, almost empty, was found in the glove compartment of the pickup truck. Breithaupt was taken to a hospital, and, while he was unconscious in the emergency room, the smell of liquor was detected on his breath. A state patrolman requested that a sample of Breithaupt's blood be taken. While he was still unconscious, an attending physician withdrew a sample of about 20 cc. of blood with a hypodermic needle. This sample was delivered to the patrolman, and subsequent laboratory analysis showed this blood to contain about 0.17% alcohol.

Breithaupt was thereafter charged with involuntary manslaughter. Testimony regarding the blood test and its result was admitted into evidence at trial over Briethaupt's objection. This included testimony of an expert that a person with 0.17% alcohol in his blood was under the influence of intoxicating liquor. Breithaupt was convicted and sentenced for involuntary manslaughter. He did not appeal the conviction. Subsequently, however, he sought release from his imprisonment by a petition for a writ of habeas corpus to the Supreme Court of New Mexico. That court denied the writ, and Breithaupt appealed to the United States Supreme Court. He contended that his conviction, based on the result of the involuntary blood test, deprived him of his liberty without that due process of law guaranteed him by the 14th amendment to the United States Constitution. It was argued on behalf of Breithaupt that the result of the blood test constituted an unreasonable search and seizure and that the introduction of the test result compelled him to be a witness against himself.

Breithaupt urged that the conduct of the state officers offends that 'sense of justice' of which the Court spoke in *Rochin* v. *California* (342 U. S. 165 [1952]). In that case state officers broke into the home of the accused and observed him place something in his mouth. The officers forced open his mouth after considerable struggle in an unsuccessful attempt to retrieve whatever was put there. A stomach pump was later forcibly used and among the matter extracted from his stomach were found narcotic pills. The Supreme Court there held that "this course of proceeding by agents of government to obtain evidence is bound to offend even hardened sensibilities." The conviction in the Rochin case was set aside because such conduct 'shocked the conscience' and was so "brutal" and "offensive" that it did not comport with traditional ideas of fair play and decency and therefore was offensive to due process.

However, in a 6-to-3 decision [1] the majority of the Supreme Court held that there was nothing comparable here to the facts in the Rochin case. The Court was of the opinion that basically the distinction rests on the fact that there is nothing "brutal" or "offensive" in the taking of a sample of blood when done, as in this case, under the protective eye of a physician. The Court said that, although Breithaupt was unconscious when his blood was taken, the absence of conscious consent, without more, does not necessarily render the taking a violation of constitutional right. Justice Tom Clark, who stated the opinion of the majority, went on to say:

> It might be a fair assumption that a driver on the highways, in obedience to a policy of the State, would consent to have a blood test made as a part of a sensible and civilized system protecting himself as well as other citizens not only from the hazards of the road due to drunken driving, but also from some use of dubious lay testimony. In fact, the State of Kansas has by statute declared that any person who operates a motor vehicle on the public highways of that State shall be deemed to have given his consent to submit to a chemical test of his breath, blood, urine, or saliva for the purpose of determining the alcoholic content of his blood. If, after arrest for operation of a motor vehicle while under the influence of intoxicating liquor, the arresting officer has reasonable grounds for the arrest, and the driver refuses to submit to the test, the arresting officer must report this fact to the proper official who shall suspend the operator's permit.

The Court concluded, in affirming the decision of the Supreme Court of New Mexico, that a blood test taken by a skilled technician is not such "conduct that shocks the conscience" or such a method of obtaining evidence that it offends a "sense of justice."

> As against the right of an individual that his person be held inviolable, even against so slight an intrusion as is involved in applying a blood test of the kind to which millions of Americans submit as a matter of course nearly every day, must be set the interest of society in the scientific determination of intoxication, one of the great causes of the mortal hazards of the road. And the more so since the test likewise may establish innocence, thus affording protection against the treachery of judgment based on one or more of the senses.

In his dissenting opinion, Chief Justice Warren observed:

> Since there clearly was no consent to the blood test, it is the nature of the invasion of the body that should be determinative of the due process question here presented. We should, in my opinion, hold that due process means at least that law-enforcement officers in their efforts to obtain evidence from persons suspected of crime must stop short of bruising

> the body breaking skin, puncturing tissue or extracting body fluids, whether they contemplate doing it by force or by stealth

In a separate dissenting opinion, Justice Douglas took this position, in which he was joined by Justice Black

> As I understand today's decision there would be a violation of due process if the blood had been withdrawn from the accused after a struggle with the police But the sanctity of the person is equally violated and his body assaulted where the prisoner is incapable of offering resistance as it would be if force were used to overcome his resistance In both cases evidence is used to convict a man which has been obtained from him on an involuntary basis And if the decencies of a civilized state are the test, it is repulsive to me for the police to insert needles into an unconscious person in order to get the evidence necessary to convict him, whether they find the person unconscious give him a pill which puts him to sleep, or use force to subdue him

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

POSTGRADUATE COURSES

The following postgraduate courses, not previously listed in THE JOURNAL, have been reported to the Council

A five-day lecture program on pediatrics will be presented June 11 to 14 at the University of California School of Medicine, San Francisco Topics will include endocrinological and growth problems, steroid therapy, obesity, newer etiological agents of childhood infectious disease, status of poliomyelitis vaccine, purpura, congenital heart disease, and pediatric dermatology The fee is $60 Information may be obtained from Dr Seymour M Farber, University of California Medical Extension, Third and Parnassus avenues, San Francisco 22

On June 21 and 22, the University of California Extension and the University of California School of Medicine at Los Angeles will present a course on hospital disaster plans at the University of California Medical Center, Los Angeles The course is sponsored by Medical Education for National Defense (MEND), hence there will be no fee Topics of the course include the role of the individual hospital in statewide disaster planning, hospital disaster plans, public health problems in episodes of natural disaster, and resuscitation of large numbers of seriously injured people Guest faculty will include medical officers from military medical centers Physicians, hospital personnel, and others interested in attending the two-day conference should obtain registration blanks from Dr Thomas H Sternberg, Assistant Dean for Postgraduate Medical Education, University of California Medical Center, Los Angeles 24

The University of Mississippi School of Medicine and the Mississippi Academy of General Practice are co-sponsoring a one-day symposium on diarrhea, June 13, at the University Medical Center in Jackson There is no registration fee for this lecture and open-question-period course The faculty will include guest instructors from other medical centers

A 1-day 6-hour course, Clinical Cardiology, for physicians in general practice and part-time specialty practice will be offered June 3, by the University of Washington School of Medicine, Seattle, for a fee of $20 Educational methods used will include patient demonstration, seminar, panel discussion, lecture, and open question periods There is no limit placed upon the number of enrollments

Also at the University of Washington School of Medicine, there will be a 3-day 15-hour course, the Chemotherapy of Malignancy, beginning Aug 8, 1957, for a fee of $25 This entirely lecture course is designed both for physicians in general practice and for those in full-time specialty practice

A six-month postgraduate course, Physical Medicine and Rehabilitation, will begin July 1, 1957, at the Highland View Cuyahoga County Hospital, Cleveland, in cooperation with Western Reserve University This course is designed for specialists in physical medicine as well as for those physicians now in residency training in this field It will consist of three sections Section 1, continuing for six weeks, will include 42 hours of lecture, 24 hours of conference, and 114 hours in wards and clinics Each student's program will be planned individually so that he may concentrate his nondidactic training hours on those subjects most closely relating rehabilitation to his own private practice or study Section 2, lasting 12 weeks, will include 64 hours of lecture, 72 hours of conferences, 162 hours in wards and clinics, and 54 hours in affiliated facilities Section 3, lasting 8 weeks, will include 32 hours of lecture, 40 hours of conferences, and 168 hours in wards and clinics Inquiries should be addressed to Dr Charles Long II, Department of Physical Medicine and Rehabilitation, Highland View Cuyahoga County Hospital, Harvard Rd, Cleveland 22

MEDICAL NEWS

CALIFORNIA

Technicians Symposium—University of California Extension will hold its sixth annual medical technicians symposium June 22-23 in the Life Science Building Auditorium at University of California, Los Angeles Subjects to be covered will be Techniques and Theory of Urine Examinations,' by Dr Ralph Goldman, Veterans Administration Hospital, Sepulveda, "Enteric Bacteriology, by Dr Charles M Carpenter, Los Angeles, and 'Advances in Blood Clotting Mechanism Techniques by Dr Samuel I Rapaport, Veterans Administration Hospital, Long Beach Fee for the conference will be $20 Information is available at offices of University of California Extension (Medical), Los Angeles 24

Personal—Dr Jerome W Shilling, was made president of the Industrial Medical Association at the annual meeting in St Louis He has been in charge of the medical department for the Pacific Telephone and Telegraph Company since 1931 ——The Association of State and Territorial Health Officers has conferred the Arthur T McCormack award on Dr Wilton L Halverson, Los Angeles (Glendale), former California State Director of Public Health, and professor emeritus, University of California, in recognition of his 'distinguished service in the fields of local, state and international health" Dr Halverson is a past-president of the Association of State and Territorial Health Officers

DISTRICT OF COLUMBIA

Freedmen's Hospital Alumni Meeting—The 35th annual meeting of the Association of Former Internes and Residents of Freedmen's Hospital will be held at the hospital June 4-6 The scientific meetings and exhibits will be in the auditorium of the Biology Building of Howard University The program committee consists of Drs Clarence S Greene, chairman, Mitchell W Spellman, Walter L Henry Jr , Coleridge M Gill, and Albert R Hughes More than 1,000 physicians have received their hospital training at Freedmen s Hospital during the past 63 years

Establish New Hospital Departments—Dr John M Orem, president, board of trustees, Sibley Memorial Hospital, announced the establishment of two new departments for the proposed new Sibley Hospital The units, not originally included in building plans, are a department of ophthalmology under Dr William M Hart, clinical associate professor of ophthalmology, Georgetown University School of Medicine, and a department of psychiatry under Dr Zigmond M Lebensohn, associate professor of psychiatry, Georgetown University School of Medicine Sibley Memorial Hospital, which will be a 350-bed hospital and has become an integral part of the American University, will have the seventh floor of its new building given to the two projected units The arrangements will make possible a training program for eye surgeons The psychiatry unit will have 28 beds

ILLINOIS

Telecasts on Health and the Weather—A new television program, "How to Live with the Weather," was recently begun at the University of Illinois, Urbana, on the university television station WILL-TV Dr Frederick Sargent II, associate professor, department of physiology, gives the weather forecast twice a week and then discusses the relation of the coming weather to human health and behavior His comments are drawn in part from folklore selected to fit the forecast and he provides the basis of each proverb given When the weather is not going to change appreciably, Dr Sargent deals with general topics such as clothing, ventilation, air-conditioning, history, physiology of heat regulation, spring fever, and the like

Chicago

Michael Reese Alumni Meet—The annual reunion of the Michael Reese Hospital Alumni Association will be held May 31 The program will include morning clinics and lunch at Michael Reese Hospital and a banquet at the Furniture Club in the evening (cocktail party at 6 30 p m) For information write Michael Reese Hospital Alumni Association, 29th Street and Ellis Avenue, Chicago 16

Hospital News—Mercy Hospital announced receipt of $84,950 from the Ford Foundation recently, representing the final payment in the foundation's nationwide hospital grants program In June, 1956, Mercy Hospital received a similar grant of $84,950, constituting the first half of the total grant given the hospital by the foundation Under the 200 million dollar hospital program announced on Dec 12, 1955, Mercy Hospital became one of many Illinois hospitals to share in the grant

MASSACHUSETTS

Dr Shattuck Honored—The Government of Cuba has presented to Dr George C Shattuck, Boston, the National Order of Merit Carlos J Finlay in the grade of Commander The Cuban National Order of Merit Carlos J Finlay was established by Presidential Decree in 1928, to honor the memory of the Cuban scientist, Carlos J Finlay The order is given to persons of any nation who have rendered outstanding service to the cause of sanitation and public welfare of the Republic of Cuba Each year on Dec 3, the birthdate of Dr Finlay, awards are made in a ceremony held in the Academy of Sciences in Havana

---

Physicians are invited to send to this department items of news of general interest, for example those relating to society activities, new hospitals education and public health Programs should be received at least three weeks before the date of meeting

MICHIGAN

Society News—At the recent annual meeting of the Detroit Dermatological Society, the following officers were elected president, Dr Coleman Mopper, president-elect, Dr George B Sexton, secretary-treasurer, Dr Alice E Palmer, recorder Robert E Burns All are residents of Detroit, except Dr Sexton, who is a resident of London, Ontario Canada

Annual Clinic Day—The eighth annual Clinic Day sponsored by Bon Secours Hospital, Grosse Pointe, will be held June 12 Papers will be presented by local staff members The occasion is in honor of Dr Elisha J Tamblyn, director of medical education, for his continuing service to the hospital Members of the medical profession are invited

Dr Conn Honored—Dr Jerome W Conn, professor of internal medicine, University of Michigan Medical School, Ann Arbor and chief of the endocrinology and metabolism unit at University Hospital, has been awarded the Claude Bernard medal from the University of Montreal's Institute of Experimental Medicine and Surgery He received the award while serving as the annual Claude Bernard visiting professor at the University of Montreal The honor is in recognition of work which led to the description two years ago of primary hyperaldosteronism

NEW YORK

Military Surgeons Meet—The New York Chapter of the Association of the Military Surgeons of the United States will hold its annual spring meeting at Governors Island June 6 at 6 00 p m The principal speaker will be General Dan C Ogle, Surgeon General of the United States Air Force, who will speak on 'Human Aspects of Flight into Space" The meeting will include a cocktail party and dinner to which guests may be invited For information write Capt Samuel Candel, MC, USNR, Secretary, New York Chapter Association of Military Surgeons of the United States, 189 Ocean Avenue, Brooklyn, N Y

Scholarships for Professional Study—Each year the State of New York awards 100 scholarships to preprofessional students for study in medicine and dentistry The examination for the next series of awards will be held on June 10 Students planning to enter medical or dental school in September, 1957, or in September, 1958, will have no other opportunity to take the examination The next examination will be held in October, 1958 The 100 scholarships are distributed on the basis of 36 medical and 14 dental scholarships to candidates residing in the counties of New York City, and an equal number to candidates residing in the other counties of the state Each scholarship is in effect for four years while the holder is attending an approved medical or dental school in New York State Information may be obtained from the Bureau of Examinations and Testing, State Education Department, Albany, N Y

NORTH CAROLINA

University News—The United States Public Health Service has made a two-year grant of $19,768 to Dr Walter R Benson of the University of North Carolina School of Medicine The funds will be used for research of the effects of disturbance of amino acid metabolism on protein formation growth and tumor formation in animals

Farm Fatalities Highest in State—Farming ranks as North Carolina's most hazardous occupation, it was revealed in figures released by the Accident Preventions Section of the North Carolina State Board of Health There were 104 residents of the State who died in farm mishaps during 1956 During the same period about 130 persons died in all other types of occupational accidents combined The accident report showed a total of 35 drownings on farms Accidents involving machinery took the lives of 28 residents, firearms, 11, and being struck by falling objects, 9 residents

OHIO

Personal—Dr Hans W Lawrence, medical director, Procter and Gamble Company, Cincinnati, was chosen president-elect of the Industrial Medical Association at its annual meeting in St Louis recently

Taylor Memorial Scholarship—The Cleveland Health Museum has awarded the 1956 Lester Taylor Memorial Scholarship ($500) to Mr George Hanosh, Detroit The scholarship is given each year by the women's committee of the museum to a graduate student interested in health education The winner spends three months at the museum, working with the staff on an original project Working with school officials and the museum staff, Mr Hanosh will plan the incorporation of small health museums within school buildings He will then design materials, such as charts, posters, and simple exhibits, for use in this type of museum These will serve as a preview to exhibits and lessons given at the museum and will bring health education to children who are not able to visit the museum itself

OREGON

Dr Saslow Goes to Portland—Dr George Saslow, clinical professor of phychiatry, Harvard Medical School, Boston, has been named to head the department of psychiatry, University of Oregon Medical School, Portland, effective June 1 He succeeds Dr Henry H Dixon, Portland, who will continue on the staff as clinical professor of psychiatry Dr Saslow presently is a consultant to the Surgeon General, U S Army and is on the steering committee, Office of Naval Research Study Section of the U S Public Health Service He was psychiatric consultant to the Los Alamos Medical Center from 1950 to 1955 and was director of the division of psychosomatic medicine, Washington University School of Medicine, St Louis

PENNSYLVANIA

Personal—Dr Richard Schatski, Brookline, Mass, gave the recent third annual Reilly Memorial Lecture at the annual meeting of the Pennsylvania Radiological Society held in Williamsport

Cardiovascular Grant—The John A Hartford Foundation, Inc, has awarded a grant of $343,800 to the Hospital of the University of Pennsylvania School of

Medicine for research in anesthesia methods, cardiac lesions, and lesions of the blood vessels The studies will be conducted under the direction of Dr Isidor S Ravdin, chairman of the surgery department, Dr Francis C Wood, chairman, department of internal medicine, and Robert D Dripps, chairman, department of anesthesiology

WISCONSIN

Theobald Smith Prize —Paul F Clark, Ph D , emeritus professor of medical microbiology, University of Wisconsin Medical School, Madison, has established the Theobald Smith prize of $100 to be awarded annually to the graduating medical student who submits the best experimental thesis Dr Clark has donated a total of $1,000 to make the prize possible for 10 years The winning student will be selected by a faculty committee Theobald Smith, who died in 1934, was a noted pathologist at Harvard and Princeton universities He discovered that Texas cattle fever, which was ruining the American cattle industry in the late 19th century, was caused by a parasite passed from one animal to another by ticks

Foreign Scholars Attend Education Conference —Fifty foreign scholars will attend a conference on medical education to be held at the University of Wisconsin Medical School, Milwaukee, June 24-26 University Medical School faculty and about 20 guest speakers from medical schools throughout the country will discuss the philosophy and practice of American medical education and lead sessions to answer questions Six national agencies are sponsoring the conference the China Medical Board, the Rockefeller Foundation, the Kellogg Foundation, the Fulbright Committee, the Association of American Medical Colleges, and the U S Department of Health, Education, and Welfare The two-day conference will be divided into lecture, discussion, and recreation periods Topics by out-of-state speakers include "The Philosophy of United States Higher Education," by Henning Larsen, Ph D , vice-president, University of Illinois, The Education of a Physician in the United States," by Dr Edward L Turner, secretary, Council on Medical Education and Hospitals, American Medical Association, "Evaluation of the Applicant for Medical Education," by Dr Robert J Glaser, dean, University of Colorado Medical School, and "Recent Trends in Medical Education,' by Dr T Hale Ham, coordinator of Western Reserve University Medical School, Cleveland

GENERAL

Tuberculosis Physicians Meeting in New York —The annual meeting of the American Academy of Tuberculosis Physicians will be held June 1 at the Henry Hudson Hotel, New York City Guest speaker at the luncheon will be Dr Ezra V Bridge, superintendent, Mineral Springs Sanatorium, Cannon Falls, Minn , whose topic will be 'Chemotherapy for Patients Following Hospitalization for Tuberculosis in the United States Results of a Survey of 424 Tuberculosis Hospitals" The presidential address will be given by Dr Rupert C L Markoe, Detroit A total of 14 papers will be presented and a business meeting will follow the program Information may be obtained from Dr Oscar S Levin, Secretary, American Academy of Tuberculosis Physicians, P O Box 7011, Denver 6, Colo

Meeting on Air Pollution in St Louis —The Air Pollution Control Association's golden jubilee meeting will be held in St Louis June 2-6 Benjamin Linsky, president of the association, will present the keynote address, 'Air Pollution Control—the Past 50 Years and the Future James H Carter, smoke commissioner of St Louis, is chairman of general arrangements Special sessions will be held in the mornings and afternoons, and a general session will be held the afternoon of June 3 A conference for control officials is scheduled for June 6 For information write Harry C Ballman, Executive Secretary, Air Pollutions Control Association, 4400 Fifth Ave , Pittsburgh 13

Examination of Orthoptic Technicians —The annual examination of orthoptic technicians by the American Orthoptic Council will be conducted in August and October The written examination will be nonassembled and will take place Aug 22 in certain assigned cities under the proctorship of designated ophthalmologists The oral and practical examinations will be held Oct 12 in Chicago, just preceding the meeting of the American Academy of Ophthalmology and Otolaryngology Application for examination will be received by the office of the chairman of examinations, Dr Frank D Costenbader, 1605 22nd St N W , Washington 8, D C , and must be accompanied by the examination fee of $30 Applications will not be accepted after July 1

Schizophrenia Research Grants —Grants totalling $99,400 for 25 research projects on schizophrenia were announced recently by F Barry Ryan Jr , president of the National Association for Mental Health An additional $1,000 has been earmarked as stipends for medical students to spend this summer in psychiatric research These grants were made from a special fund of $110,000 provided by the Supreme Council, 33rd Degree, Scottish Rite Freemasonry Of this amount, $100,000 has been contributed by the organization's Northern Masonic Jurisdiction and $10,000 by its Southern Masonic Jurisdiction The research program is being directed through the National Association for Mental Health A total of more than $1,210,000 has already been contributed by the Scottish Rite for research in the causes and treatment of schizophrenia

Announce Behavioral Research Grant —A pilot training and research program, stressing the interrelation of many branches of the biological and physical sciences as the key to a better understanding of the nervous system and human behavior, has been initiated at the Albert Einstein College of Medicine of Yeshiva University, New York City, as a result of a $1,700,000 grant made by the National Institute of Mental Health, U S Public Health Service Announcement of the grant, which covers a six-year period, was made by Samuel Belkin, Ph D , president of Yeshiva University Provision is made for awarding 36 fellowships on both predoctoral and postdoctoral levels The program will mark a new emphasis in both medical education and research by cutting across departmental lines and promoting an interwoven pattern of scientific research and thinking

Medical Cruise to Scandinavia—Duke University School of Medicine, Durham, N C, will conduct a postgraduate seminar cruise to Scandinavia, Aug 20-Sept 9, sailing aboard the Swedish luxury liner M S Stockholm, from New York The medical program will constitute 30 hours of acceptable category I postgraduate requirements of the American Academy of General Practice The faculty will include Drs William M Nicholson, associate professor of medicine, Deryl Hart, professor of surgery, W Banks Anderson, professor of surgery (ophthalmology), John E Dees, professor of urology, Susan Coons Dees, associate professor of pediatrics, and Julian M Ruffin, professor of medicine Stops will be made in Dublin, Edinburgh, Bergen, and Copenhagen Medical seminar meetings will be held aboard ship and in Edinburgh, Oslo, and Copenhagen For information write Dr William M Nicholson, Director, Postgraduate Education, Duke University School of Medicine, Durham, N C

Angiologists Meet in New York—The North American Chapter of the International Society of Angiology will hold its fifth scientific meeting June 1 at the Biltmore Hotel, New York City A symposium, 'Present Status of Surgical Management of Cardiac Valvular Insufficiencies,' is scheduled, with the following participants presenting various aspects Dr Jesse E Edwards, Rochester, Minn, the patho-physiologic aspects, Dr Samuel G Blount Jr, Denver, the medical aspects, Dr Dwight E Harken, Boston, the surgical management of mitral insufficiency, and Dr Charles A Hufnagel, Washington, D C, the surgical management of aortic insufficiency The presidential address, "Patent Ductus Arteriosus with Pulmonary Hypertension," will be presented by Dr Harris B Shumacker Jr, Indianapolis Invited speakers and their topics include Drs Milton F Bryant and John M Howard, Atlanta, 'Experimental Evaluation of Grafts Used to Replace Short Segments of Veins," and Drs Theodore I Jones and W Andrew Dale, Rochester, N Y, Study of Peripheral Autogenous Vein Grafts" For information write Dr Henry Haimovici, Secretary, International Society of Angiology, North American Chapter, 105 E 90th St, New York 28

Plastic Surgery Scholarships—The Foundation of the American Society of Plastic and Reconstructive Surgery, recently announced its 1957 scholarship contest Three groups of candidates are to be considered (1) Junior classification—restricted to residents in training, and plastic surgeons who have been in practice no longer than five years, two awards, a six-month and a three-month scholarship, are offered, character references by two leading plastic surgeons must accompany the manuscript (2) Senior classification—contestants must be in active practice of plastic and reconstructive surgery for more than five years (3) Original contributions in plastic surgery field submitted by non-plastic surgeons—a silver plaque or certificate of honorable mention is offered for a winning essay in classifications two and three Manuscripts should be sent by registered mail to the award committee before June 1 The subject matter of the essay must be the result of some original research in plastic and reconstructive surgery and about 5,000 words in length and unpublished All essays shall be submitted in quadruplicate An additional envelope shall include the contestant's name, address and affiliation, with details of professional training and percentage of practice in plastic surgery Send manuscripts to Dr Richard B Stark, 20 E 68th St, New York 21, N Y For information write the Foundation of the American Society of Plastic and Reconstructive Surgery, Inc, c/o Dr Clarence R Straatsma, President, 5 E 83rd St, New York 28, N Y

Establish Registry of Pediatric Pathology—The chairman of the committee on pediatric pathology of the American Academy of Pediatrics has announced that under the auspices of the American Academy of Pediatrics, a special registry, devoted to pediatric pathology, is to be established as a component of the American Registry of Pathology of the Armed Forces Institute of Pathology The advantages of a registry of pediatric pathology accrue from the special character of pathology as seen in children The registry of pediatric pathology will limit its material only with respect to the age group involved Adequate cataloguing, maintenance of records and availability of material are primary objectives in the procedure A consultation service will be provided for all pathologists, similar to that offered by the other component registries Leading authorities in pediatric pathology in this country and abroad will thus be on call for questions in their special fields of interest The material will also be made available for teaching purposes and it is hoped that in the future, the registry may provide a position for training in pediatric pathology The support of all pathologists and pediatricians, is said to be needed to insure the success of this new division Inquiries concerning it should be addressed to the Registry of Pathology at the Armed Forces Institute of Pathology, at Walter Reed Medical Center, 6825 16th St, N W, Washington 25, D C All interested physicians are invited to visit the registry The committee on pediatric pathology of the American Academy of Pediatrics consists of Drs Sidney Farber, professor of Pathology, Harvard Medical School, Boston, chairman, Edith L Potter, associate professor of obstetrics and gynecology, University of Chicago, the School of Medicine, Chicago, Irving J Wolman, associate professor of pediatrics, University of Pennsylvania School of Medicine, Philadelphia, William B Kiesewetter, associate professor of surgery, University of Pittsburgh School of Medicine, Pittsburgh, George H Fetterman, associate professor of pathology, University of Pittsburgh School of Medicine, Pittsburgh, Robert S Cleland, Los Angeles, Major Danield Stowens, MC, of the Armed Forces Institute of Pathology, is secretary of the committee

CORRECTION

Management of Intracranial Bleeding—Concerning his article in The Journal, March 30, 1957, Dr Maurice L Silver writes that the sentence beginning with the word "Emergency," nine lines from the end of the small print under "Case 3," page 1099, should read as follows "Emergency intubation and surgical exploration were without avail, and the patient died Emergency exploratory examination revealed the ruptured vascular malformation, with evidence of a large clotted hematoma and additional fresh bleeding extending through the brain to the brain stem"

GOVERNMENT SERVICES

AIR FORCE

New Air Force Hospital in Libya—The new air-conditioned 150-bed U S Air Force Hospital, recently dedicated at Wheelus Air Base near Tripoli, Libya, has five wards, an administrative wing, and outpatient, pharmacy, laboratory, x-ray, and physical therapy departments The hospital is capable of providing complete services to military personnel and dependents in the area, with the exception of orthopedic surgery, otolaryngology, and ophthalmology, however, these services are covered by consultants from the 7100th U S A F Hospital in Germany The new hospital is tied in with a widespread air evacuation system and will serve members of the armed services and their families from Morocco to the Burma border The hospital is authorized 52 officers, 128 airmen, 4 Air Force civilians, and 34 native positions Functioning as an area hospital in support of medical installations in Greece, Turkey, Crete, and Saudi Arabia, it will provide hospitalization or outpatient treatment for patients evacuated by air from these areas

It happened that a group of military and civilian doctors who were on a four-week nutrition study tour through 10 Middle Eastern and Near Eastern countries were in Tripoli last November and were able to attend the dedication ceremonies Among them were Dr Frank B Berry, Assistant Secretary of Defense, Rear Adm Bartholomew W Hogan, surgeon general of the U S Navy, Major Gen James O Gillespie, from the office of the Army Surgeon general, Dr Richard A Kern, professor of medicine, Temple University Medical School, Philadelphia, Dr Edward Churchill, professor of surgery, Harvard Medical School, Boston, Major Gen Harry Armstrong, surgeon, U S Air Forces in Europe, and prominent members of the Interdepartmental Committee on Nutrition for National Defense

Air Force Commissions—The surgeon general's office reports that scores of inquiries are being received from physicians who are noncitizens and/or graduates of foreign medical schools and who are interested in commissions in the Air Force Medical Service A wide range of nationalities is covered, and the persons are graduates of a number of foreign nonaccredited medical schools

To qualify for appointment in either the reserve or regular component of the Air Force, the applicant must be a graduate of a medical school accredited by the Council on Medical Education and Hospitals of the American Medical Association The applicant must be a citizen of the United States However physicians who are noncitizens and are special registrants under the Universal Military Training in Service Act, as amended, may be tendered temporary appointments if they are scheduled for induction and are allocated to the Air Force These physicians must have completed at least one year of approved internship or residency training and must be licensed to practice medicine in a state or territory of the United States or in the District of Columbia

New U S A F Hospital at Wheelus Air Base in Libya

ARMY

Suggestions for Medicare—Suggestions for a revision of the "Statement of Services Provided from Civilian Sources," DA Form 1863, have been called for by Major Gen Paul I Robinson, executive director of the Medicare program Considerable comment has been received by his office with respect to certain inadequacies and complexities of the existing form Recognition of the importance of a well-designed and adequate form for the payment of hospitals and physicians has prompted the Office for Dependents' Medical Care to take immediate action to improve the form's format

Any and all suggestions are welcome In order to redesign and make the form final without delay, General Robinson has asked that comments and layout designs be submitted to his office not later than May 15, 1957

Dr Hilleman Receives Award—In recognition of his contribution to medicine and to the Department of Defense, Dr Maurice A Hilleman of the Walter Reed Army Medical Center, Washington, D C, received from Secretary of Defense, Charles Wilson, on April 18, a citation and an award for his discovery of the RI-67 group of viruses, which have been found responsible for many cases of respiratory disease Five other distinguished civilian service awards were presented to scientists in other fields by the Secretary of Defense on April 18 Present at the ceremony were the several secretaries of military departments, key officials and officers of their staffs, and members of the families of the award recipients

In a symposium before the Section on Experimental Medicine and Therapeutics, June 4, during the Annual Meeting of the American Medical Association in New York, Dr Hilleman will present a paper on "Vaccination Against Adenovirus Infections" He also will have a scientific exhibit on this subject during the meeting

NAVY

New Reserve Consultants—Dr William L Rogers, San Francisco, and Dr Gordon M Bruce, New York City, have accepted invitations to serve on the Board of Reserve Consultants to the Bureau of Medicine and Surgery, representing, respectively, the specialties of surgery and ophthalmology Some 17 other consultants from various parts of the country serve on the board, which meets in Washington from time to time, to advise the surgeon general on the graduate training program of the Navy Medical Corps, and to assist in choosing consultant lecturers to the staffs of naval hospitals and similar advisory duties

VETERANS ADMINISTRATION

Home-Town Pharmacy Program—The VA's home-town pharmacy program supplements the VA pharmacy services in providing outpatient prescription service for veterans under treatment by private physicians for service-connected disabilities In 46 states and Hawaii, retail pharmacies participate in this program through state pharmaceutical associations In Rhode Island and Nevada, the retail pharmacies participate through direct arrangements with the VA The state pharmaceutical associations are paid a fee for administering the program, this is a percentage of the total value of prescriptions handled and is added to the basic prescription price charged by the pharmacist

The director of the pharmacy service at the VA central office, Washington, D C, Vernon O Trygstad, said that the annual volume of the prescriptions filled by retail pharmacies in the fiscal year 1956 was $2,687,693, and that if the current prescription volume continues throughout the remainder of the present fiscal year it will exceed that of the 1956 total He also said that, while the actual number of prescriptions fillled in 1956 by retail pharmacies decreased by 5%, the dollar volume remained about the same because the prescriptions, although fewer, often were for larger quantities of drugs

Personal—Dr Chalmer Davee, director, professional services, VA Center, Hot Springs, S D, has been appointed manager of the VA Hospital, Marion, Ill, succeeding Dr Edward A Welch, who retired April 30 The hospital is a 176-bed general medical and surgical facility

Dr F William Henderson has been reassigned as chief, medical service, at the VA Hospital in Lake City, Fla, succeeding Dr J A Baird, who retired

Staff Positions Available—The VA Hospital, Houston, Texas, will be opening 212 beds for psychiatric and tuberculosis-neuropsychiatric patients after July 1, 1957 Full-time staff positions, as well as regular and career residencies, are available The hospital's teaching program is a part of the Baylor University Affiliated Hospitals Residency Program

Hospital News—Dr Currier McEwen, associate professor of medicine, New York University–Bellevue Medical Center, New York City, addressed the staff of the VA Hospital at Northport, Long Island, N Y, April 29, on 'Experiences with the Long-term Use of Corticosteroids

PUBLIC HEALTH SERVICE

Sewage Treatment Grants to One Hundred Sixty five Municipalities—The Public Health Service announced on April 17 that in the last two months additional federal water pollution control grants totaling $15,212,939 have been made to 165 municipalities to help build sewage treatment works These cities and towns, ranging in population from 269 to 353,000, will add $49,928,035 of their own funds to the federal grants Since the beginning of the program last December, a total of $19,096,474 in federal grants has been made to 225 municipalities for sewage treatment construction, and the communities are adding $61,798,723 The average project will serve a population of about 18,000 and will cost about $310,000 The average federal grant has been about $74,000

Congress last year authorized annual grants of 50 million dollars, up to an aggregate of 500 million dollars, for the construction of municipal sewage treatment works It limited individual grants to $250,000 or 30% of the total project cost, whichever is less

Poliomyelitis Vaccine —Dr Leroy E Burney, the surgeon general said, on April 12, that releases of poliomyelitis vaccine and the reports from the states indicated that the vaccine shortage had eased somewhat in the last several days He reported that 5,200,000 cc of newly produced vaccine had been released so far in April and that larger amounts were expected during the latter half of the month

The surgeon general reported that over 59 million Americans had received one or more injections since the vaccine first became available on April 12, 1955 Many of these persons, however, need second or third injections to complete the recommended schedule of three doses Dr Burney also said that the incidence of poliomyelitis so far this year is remaining well below the 1956 incidence From Jan 1 to April 5, 1957, only 528 cases had been reported as compared to 1,067 for the same period last year To date, states and territories have received $46,300,000 of the $53,000,000 in federal grants available to them under the Poliomyelitis Vaccination Assistance Act of 1955, and they expect to spend the remainder before the act expires on June 30, 1957

Begin Survey of Nation's Health —On May 6 interviewers began visiting selected households throughout the nation to obtain information for the National Health Survey, the surgeon general has announced They ask questions about illness in the family, accidents and injuries, disability, hospitalization, and medical and dental care The surgeon general said, "This is the first time in 20 years that an effort has been made to collect these facts on a comprehensive basis

The household interviewing will be done by the Bureau of the Census and will be carried on continuously Each month a different group of households will be visited Since the size of the national sample is limited to 3,000 households per month, the number of households interviewed in any one area will be small The National Health Survey is being undertaken under legislation enacted by the last Congress The information collected in the household interviews will be kept confidential, and only statistical totals will be published

New Coast Guard Medical Chief —Dr Richard B Holt, a senior career medical officer of the Public Health Service, has been appointed chief medical officer of the U S Coast Guard, effective July 1, succeeding Dr Joseph F van Ackeren, who is retiring after 31 years of service As chief medical officer of the Coast Guard, Dr Holt will hold the rank of assistant surgeon general, comparable to that of rear admiral (upper half) He will be responsible for the supervision of all physicians, dentists, and nurses detailed to the Coast Guard, and will serve as liaison officer between the Coast Guard medical program and the Bureau of Medicine and Surgery of the U S Navy Dr Holt entered the Public Health Service in 1927

Inactive Reserves —The Public Health Service announced April 28 the appointment of 172 doctors, nurses, and other professional persons to the inactive reserve component of its commissioned officer corps The service is organizing and training health and medical personnel throughout the United States and its territories for emergency duty in times of national crisis Officers of the commissioned reserve are trained to serve in critical situations affecting the health and well-being of large numbers of people In emergencies, these officers would serve in posts for which their professional training and experience have best fitted them They would be called out principally to reinforce the staffs of official state and local health agencies and to augment the Public Health Service operating staff

Study of Nutritional Status of Indians —The Public Health Service has appointed seven research and nutrition authorities to serve as consultants on the nutritional status of American Indians This committee, which plans to meet twice a year, will consider priorities for the nutrition research needed It will review nutrition research projects involving Indians that are proposed to the Public Health Service by institutions and individuals

The members of the committee are Dr William J Darby, Nashville, Tenn , Dr Olaf Michelsen, Bethesda , Md , Dr John Adair, Sandoval, N Mex , Dr Robert E Shank, St Louis , Dr Charlotte Young, Ithaca, N Y , Dr Luther L Terry, Bethesda, Md , and Miss Marjorie Heseltine, Washington, D C

Dr James R Shaw, chief, and Dr J O Dean, assistant chief, Division of Indian Health, addressed the first meeting of this committee on April 29 Dr Bertlyn Bosley, chief, nutrition section, Indian health program, was chairman of the meeting

Personal —Dr Kenneth W Chapman has been appointed associate director of the Clinical Center of the National Institutes of Health, Bethesda, Md His previous assignment was with the National Institute of Mental Health, where he was consultant to state and community hospitals and health agencies on the medical problems of narcotic addiction Dr Chapman joined the Public Health Service in 1939

DEATHS

Sigerist, Henry Ernest, formerly director of the Institute of the History of Medicine at Johns Hopkins University School of Medicine, Baltimore, died at his home in Pura, Switzerland, March 17, aged 65 Dr Sigerist was born in Paris, France, April 7, 1891 He received his medical degree at the Universitat Zurich Medizinische Fakultat, Switzerland, in 1917 and during World War I was a medical officer in the Swiss Army From 1921 to 1923 he served on the faculty of the University of Zurich as a lecturer and professor of the history of medicine In 1925 he succeeded his teacher, the late Prof Karl Sudhoff, as director of the Institute of the History of Medicine at the University of Leipzig, serving until 1932 when he came to the Johns Hopkins University School of Medicine in Baltimore succeeding Dr William H Welch as director of the Institute of the History of Medicine, serving until 1946 when he retired and became research associate in the history of medicine at Yale in New Haven, Conn Dr Sigerist had been named to Yale faculty under an unusual arrangement whereby he could live in Switzerland and engage in preparing a monumental eight-volume history of medicine He traveled widely He delivered the South African Universities lectures, the Messenger lectures at Cornell, and came to Yale in 1940 to deliver the annual Dwight Terry lectures In 1944 he served as chairman of the Saskatchewan Health Services Survey Commission and advisor to the Health Survey and Development Commission of India In 1943 he was a vice-president of the American Association for the Advancement of Science, and since 1938 was vice-president of the International Society for the History of Medicine He was an honorary fellow of the Academy of Medicine of Mexico and the New York Academy of Medicine, member of the American Academy of Arts and Sciences, American Philosophy Society, Alpha Kappa Kappa, Delta Omega, and Alpha Omega Alpha He was past-president and secretary of the American Association of the History of Medicine and of the Society of the History of Science In 1933 he was awarded the Karl Sudhoff Medal and in 1950 the William H Welch Medal of the American Association of the History of Medicine He was the author of several books, and the editor of many volumes, reports, and bulletins of foreign universities, the founder and editor for 15 years of the *Bulletin of the History of Medicine,* and from 1943 to 1948 he was editor of the *American Review of Soviet Medicine* He had been awarded the degrees of doctor, honoris causa, University of Madrid, doctor of literature from the University of the Witwatersrand, doctor of laws from Queens University, Kingston, Ont, and doctor of science from the University of London, England

Hamilton, Charles Marshall ⊕ Nashville, Tenn, born in Russellville, Ala, March 25, 1890, Vanderbilt University School of Medicine, Nashville, 1918, professor emeritus of clinical dermatology at his alma mater, formerly on the faculty of Meharry Medical College, specialist certified by the American Board of Radiology, past-president and treasurer of the Tennessee State Medical Association, serving as chairman of its board of trustees, past president of the Nashville Academy of Medicine and the Davidson County Medical Society, since 1949 member of the House of Delegates of the American Medical Association, member of the American Academy of Dermatology and Syphilology and the Radiological Society of North America, since 1953 a member of the board of hospital commissioners of Nashville, served on the staffs of the Nashville General Hospital and St Thomas Hospital, where he was president of the medical staff since 1942, died April 25, aged 67, of a heart attack on Kentucky Lake, near Camden, while fishing with friends

Engler, Clarence William ⊕ Cleveland, born in Fremont, Ohio Aug 1, 1895, Western Reserve University School of Medicine, Cleveland, 1919, specialist certified by the American Board of Otolaryngology, assistant clinical professor of otolaryngology at his alma mater, veteran of World War I, member of the American Academy of Ophthalmology and Otolaryngology, Cleveland Library Association, Academy of Medicine of Cleveland, American Laryngological Association, and the American Laryngological, Rhinological and Otological Society, president of the American Broncho-Esophagological Association, fellow of the American College of Surgeons, on the staffs of the Huron Road Hospital, East Cleveland, City Hospital, St Luke's and Lutheran hospitals, until recently president of the staff of St Vincent Charity Hospital, where he died Feb 23, aged 61, of congestive cardiac disease

Cohen, Ira ⊕ New York City, born in Long Branch, N J, in 1887, Columbia University College of Physicians and Surgeons, New York City, 1911, member of

---

⊕ *Indicates Member of the American Medical Association* the founders group of the American Board of Surgery, specialist certified by the American Board of Neurological Surgery, member of the American Neurological Association of which he was at one time vice-president, fellow of the American College of Surgeons, served as member of the New York Academy of Medicine, served in the medical corps of the U S Army on the Mexican Border in 1915, a captain in the medical corps of the U S Army in France during World War I, served on the staffs of the Mount Sinai Hospital, where he was president of the medical board, from 1942 to 1945, Hospital for Joint Diseases, and the Montefiore Hospital, died in Stratford, Conn , March 8, aged 69, of leukemia and cancer

Bonthius, Andrew ⊕ Pasadena, Calif , born in Chicago Nov 27, 1880, Northwestern University Medical School, Chicago, 1909, emeritus professor of medicine at College of Medical Evangelists Loma Linda and Los Angeles, specialist certified by the American Board of Internal Medicine, fellow of the American College of Physicians, at one time a medical missionary in China, and consular surgeon for the U S Public Health Service in Amoy, China, on the staff of the Los Angeles County Hospital, consultant, Collis P and Howard Huntington Memorial Hospital, for three years medical examiner for the Selective Service during World War II, a director of the Chamber of Commerce, died Feb 24, aged 76, of coronary occlusion

Fritzell, Kenneth Edward ⊕ Grand Forks, N D , born in Minneapolis Feb 17, 1908, University of Minnesota Medical School, Minneapolis, 1931, certified by the National Board of Medical Examiners, specialist certified by the American Board of Surgery fellow of the American College of Surgeons, past-president of the Grand Forks District Medical Association, associate professor of surgery, University of North Dakota School of Medicine, veteran of World War II, member of the staffs of St Michael s Hospital and the Deaconess Hospital, where he was chief of staff from 1951 to 1954, surgeon for the Great Northern Railway, died in the Peter Bent Brigham Hospital, Boston, Feb 19, aged 49, following an operation on the heart

Wilson, Joseph G , Senior Surgeon, U S Public Health Service, retired, Beloit, Wis , born June 23, 1874, University of Pennsylvania Department of Medicine, Philadelphia, 1898, service member of the American Medical Association, member of the American Psychiatric Association, associated with the U S Public Health Service from 1906 to July 1, 1938, when he retired, served as director of the division of hospitals and mental hygiene, state department of welfare in Kentucky, formerly connected with the National Committee for Mental Hygiene in making surveys of mental institutions in various parts of the United States, died in the Beloit Hospital Feb 5, aged 82, of bronchopneumonia and coronary sclerosis

Sturgeon, John Dawson Sr , Uniontown, Pa , born in Uniontown, July 12, 1854, College of Physicians and Surgeons, Baltimore, 1880, an associate member of the American Medical Association, the Fayette County Medical Society, of which he was for one term president and for 20 years assistant secretary, dedicated the June, 1954, issue of its publication the *Fayette County Mirror,* in honor of his 100th birthday anniversary, at one time county coroner, a member of the city s first board of health, for some time U S pension examiner, one of the founders and charter member of the staff of the Uniontown Hospital, died Feb 15, aged 102, of pneumonia

Collins, William James ⊕ Northampton, Mass , Harvard Medical School, Boston, 1898, decorated by Gen John J Pershing during World War I for exceptionally meritorious and conspicuous service" in France where he served as division surgeon and chief medical officer for the 76th Division of the American Expeditionary Forces, awarded the Purple Heart, during World War II did recruiting work for the Army Navy, and Marines, on the staff of the Cooley Dickinson Hospital where he died March 1, aged 80, of cerebral hemorrhage and arteriosclerotic heart disease

Crosby, Leonard Green ⊕ Denver, born in New Auburn, Minn Jan 26, 1873, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1899, specialist certified by the American Board of Radiology, member of the Radiological Society of North America and the American College of Radiology, past-president of the Rocky Mountain Radiological Society, veteran of World War I, on the staffs of Colorado General, Denver General, Mercy and St Luke s hospitals, and St Joseph's Hospital where he died Feb 17, aged 84, of cerebral hemorrhage

Dodd, Verne Adams ⊕ Lantana, Fla , born in Waterville, Ohio, Feb 21, 1881, Ohio Medical University, Columbus, 1903, member of the Ohio State Medical Association, fellow of the American College of Surgeons, past-president of the Columbus Academy of Medicine, veteran of World War I, emeritus professor of surgery at the Ohio State University College of Medicine in Columbus, the Ohio State University presented him with the honorary degree of LL D , formerly chief of staff of the Ohio State University Hospital in Columbus, where he died Feb 22, aged 76, of cancer

Duval, Douglas Forrest, Colonel, U S Army, retired, Annapolis, Md , born June 4, 1870, University of Virginia Department of Medicine, Charlottesville, 1894, commissioned a captain in the medical corps, regular Army, in 1903, among other places, served at the U S Military Academy West Point, Philippine Islands, Hawaii, Cuba and the Mexican border, during World War I, was commanding officer of Evacuation Hospital, number 11 France, member of the American Medical Association and fellow of the American College of Surgeons, died in the Anne Arundel General Hospital Jan 16, aged 86, of peritonitis

Gerstley, Jesse Robert ⊕ Chicago, Rush Medical College, Chicago, 1909, specialist certified by the American Board of Pediatrics, member of the American Academy of Pediatrics, past-president of the Chicago Pediatric Society, at one time member of the board of governors of the Institute of Medicine of Chicago, member of the Alpha Omega Alpha honor fraternity, veteran of World War I, served as associate in pediatrics at Northwestern University Medical School, past-president of the medical staff at the Michael Reese Hospital, where he was chairman of the pediatric department, died March 16, aged 70

Schmitt, Lionel Samuel, San Francisco, University of California School of Medicine, San Francisco, 1901, an associate member of the American Medical Association, associate professor of preventive medicine emeritus at the University of California School of Medicine, where he served as acting dean, formerly director of hospitals, University of California Hospital, a member of the California Academy of Sciences and the California Academy of Medicine, veteran of World War I, died in St Francis Memorial Hospital Feb 5, aged 79, of carcinoma of the colon and coronary arterial insufficiency

Smythe, Frank Ward ⊕ Memphis, Tenn , born in Kosciusko, Miss , Nov 18, 1891, University of Tennessee College of Medicine, Memphis, 1917, associate professor of surgery at the University of Tennessee College of Medicine, member of the founders group of the American Board of Surgery, member of the Southern Surgical Association, Central Association of Obstetricians and Gynecologists, and Southeastern Surgical Congress, fellow of the American College of Surgeons, veteran of World War I, on the staffs of the John Gaston Hospital and Baptist Memorial Hospital, died Jan 26, aged 65

Pinkley, Virgil Milo, San Bernardino, Calif , born in Geneva Nebr in 1884, Vanderbilt University School of Medicine Nashville, Tenn 1908, served as deputy health officer and later as superintendent of the San Bernardino County Hospital, retiring in 1951, at one time associated with the Indian Service, for four years president of the board of trustees of the city school, San Bernardino Valley College gave him its first annual award for meritorious service in the cause of education and civic progress, died Feb 12, aged 72, of acute myocardial infarction

Randall, Samuel Bunker ⊕ Santa Cruz, Calif , University of California School of Medicine, San Francisco, 1925, certified by the National Board of Medical Examiners, fellow of the American College of Surgeons, secretary of the Santa Cruz County Medical Society, veteran of World War I, a member of the city board of education from 1937 to 1955 and president of the school trustees from 1951 to 1955, on the staffs of Santa Cruz and Sisters hospitals, died Feb 1, aged 58, of carcinoma of the stomach with metastasis

Dinnen, James Frank, St Petersburg, Fla , Indiana University School of Medicine, Indianapolis, 1908, served as vice-president of the American Association of Railway Surgeons, from 1927 to 1943 chief surgeon for the Erie Railroad, formerly assistant chief surgeon for the Nickel Plate Road and supervising surgeon for the Chesapeake and Ohio Railroad, for many years consulting surgeon at St John's Hospital and on the staffs of St. Luke's and Lutheran hospitals, died Feb 18, aged 72

Alliaume, Charles Edward, Utica, N Y , Hering Medical College, Chicago, 1895, an associate member of the American Medical Association, member of the American Radium Society, served on the staff of St Luke's–Memorial Hospital Center, died Feb 16, aged 83

Allphin, Winfield Scott, Georgetown, Ky , Hospital College of Medicine, Louisville, 1904, member of the Kentucky State Medical Association, president of the Scott County Medical Society, member and past-president of the Rotary Club, president of the First National Bank of Georgetown, on the staff of the John Graves Ford Memorial Hospital, died in St Joseph's Hospital, Lexington, Feb 17, aged 76, of a heart attack

Anderton, Herbert Seth, San Diego, Calif , University of Maryland School of Medicine, Baltimore, 1910, an associate member of the American Medical Association, veteran of World War I, on the staff of the Mercy Hospital, on the board of the San Diego Gas and Electric Company, died Feb 15, aged 68, of coronary disease

Atchley, Barney D , Everett, Wash , Drake University College of Medicine, Des Moines, 1911, died Dec 2, aged 77

Atkinson, Curtis ⊕ Wichita Falls, Texas, Jefferson Medical College of Philadelphia, 1900, veteran of World War I, past-president of the Wichita County Medical Society, died Feb 16, aged 82

Axelrad, John ⊕ Farmingdale, N Y , Medizinische Fakultat der Universitat, Vienna, Austria, 1924, formerly owner of the Lakeside Hospital in Copiague, where he died Feb 21, aged 57, of coronary thrombosis

Bailey, Donald Middlesex ⊕ Gillett, Wis , Hahnemann Medical College and Hospital of Philadelphia, 1941, interned at Morristown (N J) Memorial Hospital, veteran of World War II, on the staff of the Community Memorial Hospital in Oconto Falls, died in Montego Bay, Jamaica, British West Indies March 9, aged 42, of coronary thrombosis

Baker, Benjamin Philo, Orlando, Fla , Medical College of Virginia, Richmond, 1948, service member of the American Medical Association, interned at Lewis Gale Hospital in Roanoke, Va , where he served a residency, captain and flight surgeon in the 321st Bomber Wing of the Strategic Air Command, died at the Pine Castle Air Base Feb 11, aged 34

Bell, Lewis Barclay ⊕ Chicago, Northwestern University Medical School, Chicago, 1911, member of the American Academy of General Practice, formerly on the faculty of his alma mater, Rush Medical College, and the Chicago Medical School, on the staff of the Jackson Park Hospital, local surgeon for the Illinois Central Railroad, died March 24, aged 72, of myocardial infarction

Bell, Walter Houston, Dozier, Ala , University of Nashville (Tenn) Medical Department, 1906, died in the Mizell Memorial Hospital, Opp, Feb 19, aged 82, of myocarditis with decompensation

Bernstein, Perry ⊕ Providence, R I, Tufts College Medical School, Boston, 1924, on the staffs of the Roger Williams General Hospital and the Miriam Hospital, where he died Feb 23, aged 58, of cerebral hemorrhage

Blackley, Carl Alvan, Lockport, N Y, Hahnemann Medical College and Hospital of Philadelphia, 1896, served as city physician, health officer, and Lockport School District physician, died Feb 19, aged 87

Blais, Robert Ernest ⊕ Amesbury, Mass, Boston University School of Medicine, 1924, interned at the Lowell (Mass) General Hospital, past-president of the North Essex Medical Society, veteran of World War II, for many years school physician, president of the medical staff of the Amesbury Hospital, where he died Feb 21, aged 59, of carcinoma of the lung

Blakeslee, Malcolm Rae ⊕ Portland, Conn, Syracuse University College of Medicine, 1925, member of the American Psychiatric Association, died in the Ellis Hospital, Schenectady, N Y, Dec 1, aged 56, of myocardial failure

Boggs, David Alexander ⊕ Wilkinsburg, Pa, University of Pittsburgh School of Medicine, 1914, veteran of World War I, on the staff of Columbia Hospital, died in the Allegheny General Hospital, Pittsburgh, Feb 28, aged 65, of postoperative anuria following replacement graft surgery for aortic aneurysm

Boone, Cassius A ⊕ Louisville, Ky, University of Louisville (Ky) Medical Department, 1913 member of the American Society of Anesthesiologists, on the staffs of the Kentucky Baptist Hospital, St Anthony Hospital, and Norton Memorial Infirmary, died in the Orange Memorial Hospital, Orlando, Fla, Feb 27, aged 69, of myocardial infarction and coronary sclerosis

Bradley, George Richard ⊕ Jacksonville, Ill, Barnes Medical College, St Louis, 1897, member of the staff of Passavant Memorial Hospital, where he died Feb 21, aged 87, of strangulated inguinal hernia and arteriosclerosis

Bronsten, Irvin Cecil, Yonkers, N Y, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1926, an associate member of the American Medical Association, served on the staff of the Lying-In Hospital and the Montefiore Hospital, New York City, where he died March 4, aged 54, of coronary disease

Burchfield, George Winston ⊕ Maryville, Tenn, Vanderbilt University School of Medicine, Nashville, 1917, specialist certified by the American Board of Otolaryngology, member of the American Academy of Ophthalmology and Otolaryngology, city commissioner, died in the Blount Memorial Hospital Feb 26, aged 62, of cerebral hemorrhage

Burket, Firm C, St Petersburg, Fla, Eclectic Medical College, Cincinnati, 1922, died Feb 13, aged 65, of myocardial infarction

Butts, Arthur Clarkson Jr, New York City, Columbia University College of Physicians and Surgeons, New York City, 1902, specialist certified by the American Board of Obstetrics and Gynecology, fellow of the American College of Surgeons, on the staff of the Fordham Hospital, died Feb 22, aged 76

Byers, Joy Cleveland, Glendale, Ariz, Northwestern University Medical School, Chicago, 1920, died Feb 18, aged 64, of a heart attack

Carhart, Earl Clyde, Los Angeles, Jefferson Medical College of Philadelphia, 1905, served on the staffs of the Angelus, Los Angeles County, and the Presbyterian Hospital-Olmsted Memorial hospitals, died in Santa Monica (Calif) Hospital March 3, aged 77, of arteriosclerosis, heart disease, and nephritis

Carpenter, Burwell S ⊕ Fairfield Ala, Medical College of Alabama, Mobile, 1905 served as a member and president of the board of education, on the staff of the Lloyd Noland Hospital, died Feb 17, aged 74, of mediastinal lymphoma

Chesne, Irving Leonard ⊕ Chicago, Loyola University School of Medicine Chicago 1919, member of the American Academy of General Practice, on the staffs of Belmont, Frank Cuneo, and Columbus hospitals, on the board of the Loyola University Alumni Association, died April 1, aged 68, of acute coronary occlusion

Clancy, Arthur William ⊕ Newburyport, Mass, Georgetown University School of Medicine, Washington, D C, 1929, veteran of World War II, on the staff of the Anna Jaques Hospital, died Feb 24, aged 54, of a heart attack

Clement, Mortimer Taliaferro, Lieut Commander, U S Navy, retired, Charleston, S C, Medical College of South Carolina Charleston, 1916, service member of the American Medical Association, joined the Navy in 1916 and retired in 1938, on the staff of the Roper Hospital, died Feb 28, aged 66, of heart disease

Cole, George Maynard ⊕ Brawley, Calif, College of Medical Evangelists, Loma Linda and Los Angeles, 1943, past-president and secretary of the Imperial County Medical Society, served as chief of staff, Pioneers Memorial Hospital, died Feb 22, aged 54

Collier, Thomas Read, Whitesburg, Ky, University of Louisville (Ky) Medical Department, 1917, member of the Kentucky State Medical Association, died Feb 21, aged 66, of coronary occlusion

Conneen, Lawrence Whelen ⊕ Portland, Maine, Georgetown University School of Medicine, Washington, D C, 1937, specialist certified by the American Board of Radiology member of the American College of Radiology, on the staff of the Bath (Maine) Memorial Hospital, Brunswick (Maine) Hospital, and Mercy Hospital, died Feb 7, aged 45

Culver, Cyrus Whitney ⊕ Washington, D C, McGill University Faculty of Medicine, Montreal, Quebec, Canada, 1910, veteran of World War I, on the staffs of Garfield Memorial and Doctors hospitals, died March 17, aged 71, of heart disease

Darling, William Adelbert, Wilson, Okla, College of Physicians and Surgeons, Dallas, Texas, 1905, died Feb 13, aged 86, of arteriosclerosis

Drury, Ray C, Chicago, Northwestern University Medical School, Chicago, 1923, fellow of the American College of Surgeons, on the staff of St Anthony de Padua Hospital, died in the Augustana Hospital March 25, aged 60, of cancer of the colon

Ebeling, Walter Wilford ⊕ Mount Vernon, Wash, University of Pennsylvania School of Medicine, Philadelphia, 1928, fellow of the American College of Surgeons, member of the American Academy of General Practice, veteran of World War II, died in the Swedish Hospital, Seattle, Feb 17, aged 55

Eckman, W Guy, Covington, Ky, Medical College of Ohio, Cincinnati, 1895, served as health officer of Covington, died in the William Booth Memorial Hospital Feb 12, aged 82

Falconer, Richard Craig, Berkeley, Calif, Medical College of Ohio, Cincinnati, 1890, for many years practiced in Lexington, Ky, where he was on the staffs of St Joseph and Good Samaritan hospitals, died Feb 27, aged 89, of heart disease

Fauley, Gordon Brown ⊕ Chicago, Northwestern University Medical School, Chicago, 1930, veteran of World Wars I and II, on the staff of the Norwegian American Hospital, where he died March 29, aged 57

Findley, William McCrea, Wilkinsburg, Pa, Western Pennsylvania Medical College, Pittsburgh, 1904, an associate member of the American Medical Association, member of the American Academy of General Practice, died in the Columbia Hospital March 6, aged 76, of cancer

Freece, Margaret A, Salina, Utah, Northwestern University Woman's Medical School, Chicago, 1897, for many years member of the school board, died in the Salina Hospital Feb 19, aged 85, of cardiac decompensation

Friedman, Peter Henry, New York City, Long Island College Hospital, Brooklyn, 1911, on the staff of the Lincoln Hospital, died in the Lenox Hill Hospital Feb 26, aged 74

Friedman, Townsend Baer ⊕ Chicago, University of Chicago, The School of Medicine, 1933, instructor in medicine, Northwestern University Medical School, specialist certified by the American Board of Internal Medicine, member of the American Academy of Allergy and the American Psychosomatic Society, veteran of World War II, chairman of the department of Allergy, Children's Memorial Hospital and Michael Reese Hospital, where he died March 6, aged 51

Fryer, Julius William, Hathorne, Mass, Medizinische Fakultat der Universitat, Vienna, Austria, 1928, member of the Massachusetts Medical Society, fellow of the American Psychiatric Association, specialist certified by the American Board of Psychiatry and Neurology, on the staff of the Danvers State Hospital, died Feb 13, aged 58

Gardiner, Waldron Raymon Jr, San Francisco, University of California School of Medicine, San Francisco, 1948, on the staff of the Stanford University Hospital, died March 6, aged 35

Goodman, James Dudley ⊕ Elyria, Ohio, Ohio State University College of Medicine, Columbus, 1939, specialist certified by the American Board of Ophthalmology, member of the American Academy of Ophthalmology and Otolaryngology, on the staff of the Elyria Memorial Hospital where he died Feb 14, aged 44, of polycystic kidney

Hagan, John Ausman, Los Angeles, Starling Medical College, Columbus, 1901, died Feb 20, aged 79, of hemiplegia and arteriosclerosis

Park, James Howard Jr ⊕ Houston, Texas, Tulane University School of Medicine, New Orleans, 1916, clinical professor of pediatrics at the Baylor University College of Medicine, specialist certified by the American Board of Pediatrics, member of the American Academy of Pediatrics, fellow of the American College of Physicians, on the courtesy staff of the Methodist Hospital, where he died Feb 6, aged 65

Parker, John Livingston, Downey, Calif, Jefferson Medical College of Philadelphia, 1906, past-president of the Imperial County Medical Society, for many years practiced in Brawley, where he was an honorary member of the Rotary Club, of which he was at one time a president, died Feb 2, aged 80

Peebles, Martha Jane, East Stroudsburg, Pa, Woman's Medical College of the New York Infirmary for Women and Children, New York City, 1897, for many years practiced in Brooklyn, where she was on the staff of the Brooklyn Hospital, served in France during World War I, formerly director of the board of health of New York City, died in Allentown (Pa) Hospital Jan 23, aged 86, of arteriosclerosis

Pitzman, Marsh ⊕ St Louis, Washington University School of Medicine, St Louis, 1906, died in the Jewish Hospital Feb 7, aged 74, of bronchiectasis and cor pulmonale

Poling, James Bishop ⊕ Lima, Ohio, Miami Medical College, Cincinnati, 1904, veteran of World War I, for many years city health commissioner, on the staffs of the Lima Memorial Hospital and St Rita's Hospital, where he died Jan 17, aged 79

Pope, Jenkins M, Edisto Island, S C, Medical College of the State of South Carolina, Charleston, 1895, died in the New Roper Hospital, Charleston, Jan 29, aged 84

Powell, Elmer Alvin, North Baltimore, Ohio, Illinois Medical College, Chicago, 1902, veteran of World War I, for many years member and president of the city and county board of education, vice-president from 1917 to 1932 when he became president of the Hardy Banking Company in North Baltimore, serving until January 1956, when he became chairman of the board, died in the Community Hospital, Bowling Green, Feb 12, aged 84

Pressly, Edward Brewster, Sparta, Ill, Medical College of Georgia, Augusta, 1950, served in the medical corps of the U S Army, formerly resident on the staff of St Joseph's Hospital, Alton, died in St Lukes Hospital, St Louis, Dec 12, aged 42

FOREIGN LETTERS

ARGENTINA

Plethora of Medical Students —The dictatorship suffered by Argentina for 12 years tended to increase the number of university students by political reasons, with an absolute disregard for the qualities or intellectual standards of the students entering the university Three factors were decisive for this increase (1) the entrance examination was abolished, (2) tuition was free, and (3) a high school diploma was not necessary for acceptance In spite of this bad situation, immediately after the fall of the dictatorship, it was not possible in Buenos Aires in 1956 to have measures for the selection of medical students adopted, although this was done at the University of Cuyo, Mendoza The total number of students in the seven medical schools of the country is 30,881, of whom 7,618 are first-year students However, the medical school in Mendoza has only 106 freshmen, and these were selected by an entrance examination Teaching was greatly improved in 1956, but because of the excessive number of students it is still difficult and unsatisfactory This is why all the professors of the medical school in Buenos Aires have requested the immediate establishment of an entrance examination for the 1957 academic year As a result, some demagogues have tried to provoke student resistance by means of strikes and public disorders The total number of physicians in the country is over 25,500, or one for each 700 inhabitants It has been calculated that by 1960 there will be 30,000, or one for each 650 inhabitants

Poliomyelitis —In 1956 there was a severe epidemic of poliomyelitis, with about 5,000 cases and a high mortality, especially in children under 2 years of age Medical groups from the United States, France, Norway, Spain, and Germany came to Argentina and promoted modern methods of treatment of the disease The Salk vaccine was given to more than 3 million children In 1956, 1,608 cases were reported in January and February, but in the same period in 1957 only 203 cases were reported

FRANCE

Pleuropulmonary Perforation —At the meeting of the Medical Society of the Hospitals in Paris on Nov 30, H Brocard and co-workers reported that pleuropulmonary perforation occurred in 3 of 40 patients with severe tuberculosis treated by deltacortisone and antibiotics They were 20, 34, and 38 years of age respectively In two, the pleural exudate did not contain any bacilli, as the perforation did not start in a caseous tubercle The speakers suggest giving hormonal treatment only to patients with recent exudative noncavitary lesions They believe that the use of hormones prevents the pulmonary parenchyma from taking the place of the substances carried away through the liquefied caseous cavity

Treatment of Intractable Pain —In *Semaine des Hôpitaux* (Jan 30, 1957), J Sigwald and co-workers present the results of their treatment of intractable pain They infiltrate the frontal lobe with procaine through a suborbital opening according to a technique of their own The operation takes about 10 minutes for each side It may be practiced in the ward Of 20 such infiltrations the results have been excellent in 7, fair in 10 and poor in 3 Although minor complications may occur, no psychic disturbance nor any alteration of personality has been observed after these infiltrations

Coenzyme A in Chronic Arteritis —At the meeting of the Medical Society of the Hospitals in Paris on Dec 7, M Perrault and F Kirsch reported their results with coenzyme A in 20 patients with chronic arteritis refractory to any of the usual treatments The new treatment failed in only two cases They gave each patient two intramuscular or intravenous injections a week of 300 mcg of coenzyme A and reduced the injected dose to 150 mcg a week as soon as improvement was noted The speakers believe that the excess of lactic acid, a toxic metabolite in the blood of patients with arteritis, is transformed by coenzyme A turned into glycogen in the muscles and the liver On the other hand, this coenzyme favors the synthesis of acetylcholine, a vasodilator

Benzopyrine in Cigarettes —The *Bulletin de l'Association française pour l'etude du cancer* (no 2, 1956) presents evidence that 3-4 benzopyrine is present in an extract of cigarette smoke The authors set up an artificial smoker, allowing it to burn cigarettes while regulating the speed of combustion They noticed that the substance extracted from the tars of the cigarette papers presents a spectrum identical to that of 3-4 benzopyrine The burning of 100 cigarette papers yielded 3 mcg of this product, but the burning of 100 cigarettes yielded only 1 2 mcg This suggests that tobacco contains some substance having an inhibitory action on the formation of 3-4 benzopyrine The authors have not yet been able to prove whether this compound is a carcinogen or only a very closely related derivative of a carcinogen

INDIA

Constituents of Urine in Health and Disease —Pain and Banerjee (*Indian Journal of Medical Research,* January, 1957) studied the total and nonprotein nitrogen, urea nitrogen, ammonia nitrogen, amino acid nitrogen, creatinine, creatine, and uric acid in 50 normal subjects, 25 patients with cirrhosis of liver, 25 with subacute nephritis, and 20 with hypertension The normal subjects consumed 80 to 110 Gm of pro-

---

The items in these letters are contributed by regular correspondents in the various foreign countries

tein, with an average intake of 2,100 calories per day, patients with cirrhosis and subacute nephritis took 100 to 120 Gm. of protein with a 2,200-calorie diet, and hypertensive patients took 75 to 85 Gm. of protein with a 2,400-calorie diet. Twenty four-hour urine samples were collected from each patient for three consecutive days. Cirrhotic patients excreted more amino acid nitrogen and ammonia nitrogen and less of the other constituents than normal subjects. They also excreted creatine, which was absent in the urine of normal persons and other patients studied. Patients with subacute nephritis had albuminuria. They excreted more amino acid nitrogen, but the excretion of other constituents was greatly diminished. Hypertensive patients also had albuminuria. In their specimens all the nitrogenous constituents were low, possibly because of renal failure.

Nature of Union Between Chloramphenicol and Antibodies.—C. M. Rangam and co-workers (*Indian J. M. Sc.* 11:1, 1957) reported that chloramphenicol has been found by some workers to lower the agglutinating titers of serums of patients with typhoid while others have observed contradictory results. It has been suggested that the lowering of the titers is due to a physical union between chloramphenicol and antibodies against Salmonella typhi. The authors, therefore, studied the nature of this union. They found that incubation of rabbit immune serum with chloramphenicol caused a decline in its antibody titer, which was restored to its former level by refrigeration. Alternate incubation and refrigeration with charcoal or a mixture of charcoal and chloramphenicol gave identical results. Progressively increasing quantities of chloramphenicol were demonstrable in the globulin fraction of the serums during the incubation phase and progressively diminishing quantities during the refrigeration phase. The authors' results pointed to a physical union between chloramphenicol and antibodies through adsorption.

Sarcoma of the Breast.—S. Kuruvilla (*Journal of Postgraduate Medicine,* January, 1957) reported a series of 30 patients with sarcoma of the breast. With adequate treatment, sarcoma has a better prognosis than carcinoma of the breast. The 30 patients were seen at the Tata Memorial Hospital, Bombay, during the years 1941 to 1955. In the same period there were 1,596 cases of carcinoma of the breast. The age of the patients with sarcoma ranged from 18 to 77 years, 18 being between 21 and 40 years. In all patients the presenting symptom was a lump in the breast. In six, there was a history of a previous operation for the disease. In one, there were six recurrences. Retraction of the nipple was present in one patient. Enlarged axillary lymph nodes were palpated in six patients. The duration of the symptoms varied from 1 month to 15 years. Histologically, fibrosarcoma was the commonest form of sarcoma, the other forms were cystosarcoma phylloides, lymphosarcoma, carcinosarcoma, and myosarcoma. In both fibrosarcoma and cystosarcoma phylloides there is often a history of a long-standing tumor that has suddenly started growing rapidly. Such a history was present in all the three cases of malignant cystosarcoma. Three of the four lymphosarcomas were seen in young patients. In one patient there were lumps in both breasts and a mass in the hypogastrium. Later she developed a generalized involvement of lymph nodes and subcutaneous nodules. All three cases of carcinosarcomas were of less than four months' duration when first seen. The carcinomatous and sarcomatous elements in the primary tumor were mixed, but metastases in lymph nodes showed only the carcinomatous element. One patient had bilateral lumps, one being a carcinosarcoma and the other a fibroadenoma. Metastasis to regional lymph nodes is rare in sarcomas of the breast, with the exception of carcinosarcoma and lymphosarcoma. Lymph node involvement in fibrosarcoma indicates a grave prognosis. Metastasis to bones was seen in three patients with fibrosarcoma and to the lungs in one with fibrosarcoma and in one with carcinosarcoma.

Central Council of Health.—At the meeting of the Central Council of Health held at Ranchi in December the Union Minister of Health said that good progress had been made in many fields and some notable developments had taken place. The targets laid down for nursing and ancillary personnel can be reached by intensifying the training program to overcome the shortage. The centrally aided training schemes for the training of health visitors and auxiliary nurse-midwives, which started in the first Five Year Plan, are to be continued in the second Five Year Plan. Special attention is necessary for the orientation of the workers on the village level in the fundamentals of public health and environmental sanitation. The village-level worker is in day-to-day touch with the people and has been especially trained in the proper approach to the people in order to seek their acceptance of new ideas and skills for the improvement of health and prevention of disease. Malaria control has progressed satisfactorily. Fortunately no resistance to insecticides has so far been reported in vectors, and as it usually takes a few years for such resistance to develop, an all-out effort will be made to completely eradicate malaria within the next few years. The mass BCG campaign made excellent progress until April, 1955, but it has bogged down since then because of the unsatisfactory conditions of service for the BCG staff and inadequate publicity. Other tuberculosis control measures included in the second Five-Year Plan are, however, being developed. The main features of this program, in addition to a BCG campaign, include (1) establishment of 300 fully equipped tuberculosis clinics, (2) establishment of 12 tuberculosis demonstration and training centers in association with medical colleges, (3) provision of 4,000 beds in different parts of the country, (4) establishment of a rehabilitation and aftercare center in association with large clinics, and (5) research work in collaboration with the Indian Council of Medical Research.

Although leprosy control has been slow, mainly because of the scarcity of suitably trained personnel, both medical and paramedical, of the 40 pilot project centers envisioned under the scheme, treatment and study centers and 30 subsidiary centers have been established A central leprosy teaching and research nstitute has been established in Tirumani, Madras Health education is assuming increasing importance A short training course for health educators has been nstituted at the All-India Institute of Hygiene and Public Health, Calcutta Arrangements are now almost complete for introducing an advanced course or health education specialists A family planning research and program committee has been set up to make recommendations to the government Two thousand family-planning clinics are to be opened in rural areas during the second Five-Year Plan period n association with primary health units At each urban and rural clinic contraceptives will be distributed free of charge

NORWAY

Prof Carl Muller—On the occasion of Prof Carl Muller's 70th birthday last November his former and present collaborators joined in publishing a commemorative volume composed of original articles chiefly concerned with cardiovascular diseases This volume is published as a supplement to *Acta medica scandinavica* All the 17 articles are in English The volume opens with a brief appreciation of Muller as teacher, research worker, and physician As a teacher he has been a constant source of inspiration to his pupils and assistants, and as a research worker he has a well-earned international reputation based, among other things, on his study of hereditary xanthomatosis (Harbitz-Muller's disease) and its relation to coronary disease

Penicillin Risks—Dr O K Harlem (*Tidsskrift for den norske Lægeforening*, Feb 15, 1957) sent an elaborate questionnaire to 1,215 persons who had been patients in the hospital or in a private medical practice or were employees in one of two industrial concerns They were asked if they had been given penicillin and, if so, in what way, if the penicillin treatment had been adequate, and how frequent and how intense certain complications had been Of these persons, 621 had been given penicillin This represented 67% of the 194 hospital patients but only 46% of the 325 employees in industrial concerns Only 16 persons, or 1 3%, had had complications after penicillin treatment, and among them there were only 7 whose complications (urticarial reactions) could be regarded as definitely allergic reactions due to penicillin This brings the penicillin risk down to 0 6% Only in two patients had the reaction necessitated discontinuance of the treatment In 86% the penicillin had been given by injection, in 10% by mouth, and in only 4% in the form of local applications (ointments, drops, inhalations) The comparative immunity enjoyed by the 621 persons given penicillin may partly be traced to the rarity with which penicillin was given as a local application, a procedure of which the author disapproves A classification of the persons according to age suggests that when penicillin treatment has been in use longer nearly all of the community will have become "penicillinized" Only about half the persons given penicillin had received it for four days or longer, and those who had been treated for a shorter time could hardly have been given adequate treatment Several of the recipients of penicillin had been given it on inadequate indications Harlem compares his penicillin allergy rate of 0 6% with those of several American observers whose estimates of the penicillin complication rate have ranged from 5% to 15%

Norwegian Aid for Underdeveloped Countries—Between 1950 and 1955, Norway put 75 experts in various sciences at the disposal of the United Nations A brochure issued by the Norwegian United Nations' Union gives an account of the work of seven of these experts in six countries One of them, Dr J Kvittingen, became a consultant for the combined international-national health project in Addis Ababa, Ethiopia Working at the venereal disease polyclinic and laboratory in Addis Ababa, he had to get along without fully qualified assistants most of the time He came to the conclusion that the widespread dissemination of syphilis constituted the greatest health problem in Ethiopia After the spring of 1955, excellent assistance was obtained from American-trained Ethiopian health educators, and many of the patients learned how important it is to bring the person from whom they had got their infection to the polyclinic In 1954, there were no fully qualified Ethiopian physicians in the country, and the few foreign physicians were a very mixed lot Without exception, the physicians attached to the various missions did excellent work While the Norwegian mission was stationed south of Addis Ababa, the Swedish mission was stationed to the west of the capital The medical officers of these two missions were most active, and the work they got through was impressive Among the private practitioners were many Italians who had remained in the country after the occupation

SWEDEN

Hypophysectomy for Malignant Disease—At the Serafimer Hospital in Stockholm, Professor Olivecrona and co-workers continue to operate on the pituitary body with a view to the cure, or at least the arrest, of malignant disease, particularly cancer of the breast Their latest observations (*Nordisk medicin*, Jan 24, 1957) concern a series of 75 patients In addition to 55 women and 2 men with cancer of the breast, there were 10 men with cancer of the prostate The remaining patients had a variety of malignant tumors In 5 of the 10 men with prostatic tumors, arrest or remission of the disease was noted Two of those with remission had previously undergone other endocrine treatment without benefit A remission could be claimed in 54% of the patients with cancers of the breast Almost the same percentage (56%) has been claimed by other surgeons operating on the pituitary body for malignant disease This remission rate of at least 50% may be higher than that of any other endocrine method of treatment, but Olivecrona does not therefore jump to the conclusion that hypophysectomy is necessarily superior to other methods In six patients with remission, the hypophysectomy was certainly incomplete Metastasis to the brain and extensive metastasis to the liver may possibly be contraindications to this operation as well as ages over 60 years. The mean duration of the remissions effected in the women with metastatic breast cancer was about 17 months. Remissions could be claimed for both the men suffering from metastatic breast cancer.

Chancroid.—Chancroid continues to be essentially a seaman's venereal disease imported from abroad. Its frequency has fallen to such an extent that it is now rare. In the 10-year period 1946 to 1955, only 491 such cases were reported in the whole of Sweden. A series of 260 patients, 14 of whom were women, was studied by Bjornberg and Krook (*Svenska lakartidningen*, Feb. 1, 1957). Most of the 246 male patients were seamen, and while most of them had been infected in foreign ports, all the women had been infected in Sweden. Several of the patients had had, or still suffered from, some other venereal disease, and as many as 36 also suffered from recent syphilis. Gonorrhea was also a common complication, as were scabies and pediculosis pubis. None of the 36 patients suffering also from recent syphilis had been treated with penicillin before coming to the hospital. On the other hand, there was not one case of recent syphilis among the 37 patients who had been treated with penicillin before hospital admission. In all the 37 patients, the chancroid had shown no sign of improvement with the penicillin treatment given on board ship without the benefits of an accurate medical diagnosis. Although the broad-spectrum antibiotics are undoubtedly effective against chancroid, it may be well to avoid them as they may mask a simultaneous syphilitic infection. The authors are well pleased with the sulfonamide treatment of chancroid, and they combine oral therapy with sulfonamides with local sulfonamide applications. Such treatment, persisted in for three to seven days, may be relied on to cure practically every case. The concomitant bubos yield to injections of penicillin, which does not, however, seem to have a definitely therapeutic effect on the soft chancre itself.

New Mode of Intoxication.—In September, 1955, the admission to the hospital of an emergency case of what was thought to be acute alcoholism in a 13-year-old boy led to the discovery of a rather widespread vice in boys of school age. Altogether 32 schoolboys were examined. Of these, 27 underwent sternal puncture and others underwent electroencephalography while under the influence of inhalations of "thinner," a solution much in use in the painting industry as a cleaning and solvent agent. An analysis of this solution showed that it contains ethyl and butyl acetate, ethyl and butyl alcohol, toluene, and probably some benzine. Reporting on these cases in *Svenska lakartidningen* for Jan. 4, Christiansson and Karlsson express grave concern over the psychiatric, sociological, and toxicological problems raised. Among the 32 boys, 18 had been addicted to this vice for at least six months, and there were some who had indulged in it for about five years. "Thinner" is dripped on a pad of absorbent cotton or a pocket handkerchief which is pressed against nose and mouth and then inhaled. The "thinner" is also inhaled as a spray directed against the lining of the nose and mouth. A sense of intoxication soon follows, and complete unconsciousness may occur. In 10 of the cases examined by sternal puncture, reactive changes were found in both the protoplasm and the nuclei of the blood cells, the former showing increased granulation and the latter alterations in the arrangement of chromatin. The electroencephalographic changes indicated cerebral stimulation, and it is doubtful if all the changes effected by prolonged indulgence in this vice are reversible. There is also the risk of addiction to it. This vice, known by the boys as "sniffing," is a serious matter requiring prophylactic measures, but, considering how useful "thinner" is in the painting world, it may be difficult to have restrictions imposed on its sale.

UNITED KINGDOM

Mass Radiography.—During the winter of 1955-1956, the mass radiography service of the Liverpool Regional Hospital Board carried out an intensive survey in the district of Bootle. Wide publicity was given to the scheme through the local newspapers, cinemas, leaflets, talks, loudspeakers, and door-to-door canvassing. The attendance of nearly all of the eligible school children was the most encouraging feature. The results (*Lancet*, Jan. 19, 1957) revealed that of 22,340 persons examined, 52 needed immediate treatment for tuberculosis and 580 had lesions that needed further study. Twelve cases of carcinoma, 98 of bronchiectasis, and 332 of cardiac abnormalities were also discovered. These results indicate the value of this method of case finding.

Nursing Homes.—The 1955 report of the health officer for London shows that there has been a steady decrease in the number of nursing homes from 170 in 1937 to 48 in 1955. Rising costs have been the main factor. Accommodation charges, which, before World War II, ranged from $14 to $24 a week, in 1955 ranged from $30 to $70 a week. The number of inmates in nursing homes dropped from 3,167 in 1947 to 1,091 in 1952. Fewer operations are performed in these homes and more of the beds have been used for medical cases, the chronically sick, and senile patients. Establishments where the aged are cared for fill a real need. Since in many staff positions a practical rather than a trained nurse will suffice, the smaller nursing homes might well turn their attention to the care of nonsurgical elderly patients.

Vagal Resection for Duodenal Ulcer.—Although vagal resection for the treatment of duodenal ulcer has not been generally accepted in this country, A. A. MacKelvie in the *British Medical Journal* of Feb. 9 presented an analysis of 473 consecutive cases so treated. 76% of the patients had received medical treatment for the condition as outpatients and 19% while in the hospital. Symptoms had been present for more than five years in at least half of the patients, and 33% had had either a perforation or noteworthy hemorrhage. The operation was performed through the abdominal wall after the left lobe of the liver had been mobilized. The esophagus was mobilized, at least 5 cm. of each vagus nerve was resected, and any residual twigs of the nerves carefully sought Of 118 patients on whom this operation was performed, in 28% the results were poor due to the need for later performing a gastroenterostomy to relieve gastric retention and such other symptoms as flatulence and diarrhea In view of this fact, in 332 patients the vagal resection was combined with gastroenterostomy, and an excellent result, with a mortality of only 2%, was obtained in over 90% of these patients A similar excellent result was obtained in 19 patients in whom vagal resection was combined with pyloroplasty, but vagal crush as a sole procedure in four patients produced no benefit The author believes that vagal resection with a combined gastroenterostomy or pyloroplasty is the method of choice in the treatment of duodenal ulcers

Traumatic Rupture of Extrahepatic Bile Ducts—John A McCredie *(British Medical Journal,* Feb 2, 1957) reported two cases of damage to the extrahepatic bile ducts in young children In each case the damage was the result of a traffic accident The lesion was not recognized at laparotomy In one patient a biliary fistula was present for three weeks, and in the other biliary ascites required frequent aspiration In both patients spontaneous healing took place Roentgenographic investigations, with the use of iodipamide sodium as the contrast medium revealed a normal biliary tree, and as a result of this experience the author suggests that attempts to repair recently traumatized extrahepatic ducts may increase the likelihood of stenosis In such cases, simple abdominal drainage and possibly cholecystostomy is all that is required

Car Design—In 1954 traffic accidents accounted for 5,010 deaths in Great Britain William Gissane, *(British Medical Journal,* Feb 16 1957) states that this compares favorably with figures from Germany, France, and Italy, whose populations are less than that of Great Britain The figures for these countries were 11,565, 7,539, and 5 281 respectively Although many factors may account for this difference, Gissane postulates that the popularity of small low, lightweight cars in these countries may be a factor With the return of gasoline rationing in Great Britain, these small cars are becoming increasingly popular This is to be deplored from the safety angle The author advocates the solid construction of body work with good design, incorporation of a good length of steel between the driver and anything he might hit, safe design of steering wheel, shatterproof glass, and a car high enough to give the driver a good view of the road He bases his views on many years of hospital experience and believes that the saving on gasoline may have been bought at too high a price

Treatment of Periarteritis Nodosa with Cortisone—A committee appointed by the Medical Research Council to investigate the effect of cortisone on the course of periarteritis nodosa reported *(Brit M J* 1 608, 1957) that as the prognosis of the disease is so grave, it is considered unethical and impracticable to have a treated and a control series A retrospective series of control patients treated before the introduction of cortisone was used for comparison The diagnosis in all patients admitted to the trial was proved by means of biopsy specimens Treatment with a dosage of 200 mg daily by mouth for a week, was started as soon as a positive diagnosis was made, or before, in the case of seriously ill patients This daily dosage was raised 100 mg each week until full suppression of the disease was obtained, or until the side-effects became intolerable Once suppression occurred an attempt was made to reduce the dosage to a maintenance level In patients with hypertension, which materially affects the prognosis, special care was taken if the blood urea level was over 60 mg per 100 ml or the diastolic blood pressure was over 110 mm Hg Strict comparison between the treated patients and the controls was not possible because of the much higher incidence of hypertension in the control group When the patients with hypertension were included in the comparison the results indicated that cortisone produced quicker relief of symptoms and suppression of signs in the treated group When the hypertensive patients were not included, the difference in the treated and untreated patients was small, but statistically in favor of the cortisone-treated patients The securing of a sustained suppression of outward manifestations of periarteritis nodosa required such large dosage of cortisone in some patients that troublesome side effects were produced

Penicillin in the Treatment of Breast Abscess—De Jode *(Lancet* 1 560, 1957) reports that the advent of antibiotics has not diminished the number of cases of breast abscess treated in hospital Of 68 consecutive cases seen at the London Hospital Micrococcus pyogenes was grown in cultures from 64 When childbirth had taken place in the hospital, 90% of the cultured micrococci were penicillin-resistant, whereas the figure dropped to 71% in those cases where birth had occurred at home Of 100 consecutive cases of breast abscess, 68 were lactational and 32 non-lactational Penicillin alone or with other antibiotics was used in 44 of the laboratory cases, other antibiotics alone in 4, and in the remainder of the cases no antibiotic was used When the organism in the abscess was penicillin-resistant, both the number of surgical incisions required and the healing time were increased in comparison with that in the cases in which no penicillin was given The masking of signs of inflammation may lead to serious delay in instituting drainage, with the result that an excessive amount of breast tissue is destroyed, amounting in some cases to a functional mastectomy

A further consequence of this destruction of breast tissue is the increased liability to further breast abscesses, particularly after later pregnancies Use of penicillin should be restricted to early cases of acute mastitis, and then only when the mother has not been delivered in hospital and there is therefore a reasonable chance of dealing with an organism sensitive to penicillin If there is no response in 48 hours, the use of penicillin should be discontinued Care should be taken to see that the patient is kept under supervision to ensure that the condition is cured and not merely masked When an abscess has formed, early and effective drainage is the surest way of obtaining early healing

CORRESPONDENCE

METHYLATED STEROIDS AND JAUNDICE

To the Editor —Orally given methyltestosterone has been used in clinical practice since its introduction by Foss in 1939 (*Brit M J* 2 11, 1939) both for its anabolic and for its androgen effects It was not until 1947 that Werner (*Am J Med* 3 52, 1947) suggested that its use might rarely be associated with jaundice Other reports followed (Kinsell, L W *Gastroenterology* 11 672, 1948, Werner, S C, Hanger, F M, and Kritzler, R A *Am J Med* 8 325, 1950, Wood, J C *J A M A* 150 1484-1486 [Dec 13] 1952 Van Dommelen, C K V, and Van der Steur, J C *Nederl tijdschr geneesk* 99 2732, 1955, Brick, I B, and Kyle, L H *New England J Med* 246 176, 1952) According to Werner and co-workers (ibid) the whole picture of jaundice associated with methyltestosterone seems to be due to bile stasis Biopsy showed dilated bile canaliculi in the central zones plugged with masses of bile pigment, and there was very mild hepatic cell damage in these central areas The cephalin-flocculation reaction was negative, the serum alkaline phosphatase level only moderately elevated, and the serum bilirubin value increased Although jaundice may be protracted, recovery is complete, in three patients who had recovered, renewed administration of this methylated compound only reproduced jaundice in one and, furthermore, as Gordon (Yearbook of Endocrinology, 1955-1956 Series, Chicago, Yearbook Publishers, Inc, 1956) states, "One reason for doubting the causative role of methyltestosterone is that the icterus is reported to disappear spontaneously, even when administration of the compound is continued' He had not seen a case after considerable experience with this substance

Since testosterone has not been so implicated, some pharmaceutical literature has given this as a reason for discontinuing use of methyltestosterone in favor of tablets of testosterone for sublingual or sublabial use Though testosterone when given orally is ineffective owing to deactivation by the liver, the makers and others claim that, given by the sublabial route, it is as effective as parenterally administered esters Methyltestosterone, on the other hand, is effective when swallowed and when absorbed sublabially, although it is slightly more efficient by the latter route (Foss, G L *J Endocrinol* 13 269, 1956) The metabolism of these two substances is apparently different in that methyltestosterone increases creatinuria and does not increase the 17-ketosteroid value

In a fairly extensive use of methyltestosterone with doses ranging from 5 to 150 mg daily over prolonged periods up to 10 years, it so happens that we have only encountered one possible case of jaundice which might have been attributed to methyltestosterone therapy Since for practice purposes it would be a pity to omit the use of methyltestosterone, unless its association with jaundice were shown to be a direct sequence and not merely coincidental, we felt we should try to ascertain whether any other physicians have noted jaundice associated with this therapy After letters to *Lancet* (1 1020, 1956) and the *British Medical Journal* (2 1426, 1956) on similar lines, we have received information about a further 10 cases in Britain and the Commonwealth in which there appeared to the observer to be an association between the taking of methyltestosterone and the appearance of jaundice, although in many of these cases there seemed to be good evidence that hepatic disease in some form was present before methyltestosterone was taken

We are venturing to submit this letter to THE JOURNAL to give us the opportunity of learning from its readers either in a published letter or private communication of any cases they may have encountered in their practice, whether the jaundice had any special characteristics, and whether this was direct proof or probability of cause and effect Since commencing this investigation it seems to us that the enquiry should be extended to other methylated steroids such as methylandrostenediol, methylandrostanolone, methyl 9 α-fluorohydrocortisone and 9 α-fluoro-11 β-hydroxy 17 α-methyltestosterone

BREAST CARCINOMA AND TRIETHYLENE THIOPHOSPHORAMIDE

To the Editor —An article by Bateman and Carlton (THE JOURNAL Oct 20, 1956 page 701) on the use of triethylenethiophosphoramide (thio-TEPA) presents data suggesting that this drug has unusual properties in controlling primary and disseminated carcinoma of the breast These authors maintain it is of special value when injected directly into the tumor site, although claims are also made of good effects on cerebral, osseous, and pulmonary metastases after systemic administration

Conclusions as to the value of any therapeutic procedure in patients with disseminated cancer of the breast are usually fraught with error because of the variability of the natural course of the disease, variations in the selection and size of clinical samples, and the difficulty in measuring objective regression of the disease Even when undisputed tumor regression does occur, it is necessary to determine if regression is due to the agent under investigation or to ancillary therapy, or even to late effects of previous treatment It seems apparent in the article cited that other modalities, notably irradiation, were employed concurrently with triethylenethiophosphoramide The definition of 'improvement' is not clear in this article, but one obtains the impression that, if any lesion regressed during therapy, that constituted improvement by their criteria, irrespective of the course of other tumor metastases A safer definition of tumor regression is that selected by the Subcommittee on Breast and Genital Cancer of the Committee on Research of the American Medical Association regression of major lesions without progression of any lesion or development of new lesions "

It is logical to expect local tumor regression at the site of injection of any caustic, cytotoxic or sclerosing agent, but the value of such treatment in carcinoma of the breast is very limited Isolated troublesome lesions usually can best be treated by irradiation or surgery Although triethylenethiophosphoramide is useful when injected into the pleural space for the control of neoplastic disease effusions, it does not appear to be superior to nitrogen mustard or radioactive gold Others who have used this drug do not agree that it is 'notable' for its lack of side-effects and serious bone marrow depression has been repeatedly reported

At the present time it is the consensus of those working in the field of cancer chemotherapy that triethylenethiophosphoramide is of no more value than other alkylating agents All these agents have been disappointing from the point of view of generalized tumor suppression in cancer of the breast, and their usefulness in this disease is probably limited to the control of effusions complicating metastatic disease

PROTECTIVE COATING FOR PLASTER CASTS

To the Editor —During the course of routine fracture care in a large clinic one is impressed with the high rate of destruction of plaster casts, especially by children A good number of the casts disintegrate under the strain of the writings, carvings and washings to which they are subject The frequent wettings of casts during the routine of living reduce many to the point where they resemble a soft rubber bandage Not infrequently, reapplication of casts is required More rarely, position of fractures is lost by failure of weakened plaster to maintain immobilization

It has been found that the external spraying of casts with Krylon plastic reduces these problems This Dupont plastic spray is dispensed in pressure cans and may be purchased at most paint or hardware stores for about $1 50 The spray may be applied immediately without waiting for the cast to dry One or two light applications have usually been sufficient No irritation of skin has been noticed

Approximately 75 casts have been treated by external spraying with Krylon plastic The life span of the cast was definitely increased, in fact it was found that the cast could frequently be made lighter due to the added hardness of the finish Dirt and grime may be removed by wiping with a damp cloth The glass-like surface resisted all but the most determined autograph artists An ordinary dousing with water in no way weakened the plaster

If the operator be in the mood for frivolity, casts may be coated in pink, blue, or any other color that might delight the patient's fancy Indeed, there have been several occasions when the use of this modality has helped in gaining rapport with a difficult child

SUBSCRIPTIONS FOR ABROAD

To the Editor —I have recently received the various publications of the A M A through arrangement with the Christian Medical Society, and I wish to express my deep appreciation of this wonderful help Patients come from many miles to be treated by "the American doctor " In a way we are representing the whole medical profession in America to these people For we are all that they see of American medicine at work If we fail, American medicine has failed in their eyes

I am in charge of a small mission hospital in village India Villagers look to us for the final help when all other help has failed They will not go a long way to another hospital for consultation If we can not help them, they usually go back to their village to die, hence versatility and a broad knowledge of medicine and surgery are of vital importance The publications you are sending are an immense help

Our financial resources are very limited, and our Indian doctor's is even more limited May I say that the literature vacuum is one of the biggest problems to the progress of medicine in backward areas It is comforting to know that you at home are interested in doing all you can to help in this and many other ways as we serve God and our fellow men in this remote and backward area

MISCELLANY

AMERICAN COLLEGE OF PHYSICIANS MEETING

The keynote of the annual meeting of the American College of Physicians in Boston in April was sounded by Dr Walter L Palmer, its president, who said that he did not believe that medicine was moving too fast but that many patients are expecting too much of it Modern drugs have made a valuable contribution to the practice of medicine, but to call them miracle drugs is to create a false concept in the minds of the public The most important things in medicine are still to discover the pathogenesis of the many diseases for which this is unknown or imperfectly known and to increase the accuracy of diagnosing the patient's condition Greater attention should be paid to the information obtainable through the physical examination G E Schreiner deplored the fact that many a physician today either does not have a microscope in his office or does not use it to examine the patient's blood and urine Many diagnoses would be made months or years earlier to the great benefit of the patient if such examinations were made routinely in office practice Henry I Russek warned that in the physician's zeal to use new and powerful drugs he must be sure that the cure is not worse than the disease For example, a fine balance must be struck between the amount of an anticoagulant drug necessary to prevent thrombosis and the amount that will produce bleeding The risk involved is justified when treating the more serious cases, but these powerful drugs are all too often given to patients with mild attacks and in whom the prognosis for recovery is excellent The giving of the drug only subjects such patients to a needless risk Robert P McCombs pursued this theme from another angle Persons who rush to take every new drug that is announced lay themselves open to serious drug reactions It is estimated that such reactions are 10 times as common as they were just after World War II No new drug should be taken without medical supervision, and the physician who prescribes it should be alert to detect untoward signs that may be the result of treatment

Immunity—At a panel on factors influencing resistance to infection, it was agreed that the wonder is not that people get sick but that in an environment teeming with many kinds of infectious agents so many stay well In some cases heredity is a factor in resistance to disease Resistance to infection may be weakened by a variety of causes Infection with one organism may open the door to a host of secondary invaders Pregnancy, industrial poisons, ionizing radiations, splenectomy, and diabetes mellitus are some of the other factors reducing resistance Charles A Janeway said that chicken pox, usually one of the most harmless of the childhood infections, may end fatally in a child who has been taking large doses of cortisone or related preparations

Coronary Heart Disease—David P Barr said that coronary heart disease depends on three factors heredity, sex hormones, and the amount of fat in the diet These factors control the distribution and concentration of the blood lipids that lead to coronary thrombosis The first cannot be controlled, but an understanding of the changes induced in the serum lipid spectrum by gonadal steroid administration may be useful in evaluating the greater vulnerability of men than women to coronary atherosclerosis, according to R H Furman and R P Howard Ancel Keys stated that the theory that the diet, and especially its fat content, is important in the genesis of coronary heart disease is supported by recent experimental and epidemiologic studies Fatty meals accelerate blood coagulation and inhibit fibrinolysis Extensive experiments on men on controlled diets show effects on serum cholesterol concentration that prove to be predictable from knowledge of the amounts and kinds of fats fed Attempts to show participation of dietary protein in the effects of dietary fats on cholesterol are negative The serum cholesterol differences between populations do not depend on differences in obesity or physical activity between those populations Studies on Japanese men in Japan, Hawaii, and California reveal, as predicted, a striking parallelism between the proportion of fat in the diet, concentration of cholesterol in the blood, and the frequency of severe atherosclerosis and coronary heart disease The serum cholesterol differences produced in dietary experiments on man and observed in population comparisons are usually, if not always, due to beta-lipoprotein cholesterol

New Antidiabetic Drug—R P Bradley and L P Krall reported on the oral use of a nonsulfonamide preparation that they called DBI that has the advantages over carbutamide that it is nontoxic and is of some benefit to young as well as old diabetics It lowers the blood sugar level, and its only untoward side effect appears to be nausea The daily dose is only 250 mg Among the advantages of oral treatment for diabetes is the fact that some people who need treatment do not have the intelligence necessary to give themselves sterile injections of insulin

Tuberculosis—Irving Kass stated that, since the advent of effective antimicrobial therapy, the internist is more frequently faced with the responsibility of initiating or continuing the therapy in patients ill with tuberculosis Unless the physician uses the antimicrobials properly, he can precipitate the emergence of resistance to the medicaments used Once resistance has been established, no matter how intense the subsequent therapy, sputum conversion to negativity is rarely achieved The following technique constitutes effective therapy Since isoniazid (INH) is most effective on multiplying organisms, bed rest, unless the patient's condition is toxic, is not required Similarly, collapse therapy is not used in patients who retain drug sensitivity The most effective drug therapy is administration of a combination of streptomycin for 90 days and isoniazid daily for 18 months This scheme does not result in the emergence of resistance and if the condition is initially sensitive to the medicaments, treatment failure does not occur There is no standard dosage of isoniazid Patients vary in their ability to metabolize isoniazid, thus all patients should, prior to therapy with this drug, have a microbiological assay About 50% of the patients are rapid inactivators, and effective isoniazid therapy is achieved only when aminosalicylic acid (PAS) is added to the regimen Aminosalicylic acid competes with the isoniazid for the latter's acetylating mechanism and permits a higher effective isoniazid blood level Thus effective isoniazid dosage varies and should be determined by the results of the microbiological assay J L Badger said that, although fewer patients are dying of tuberculosis, the number of active cases, many of them unattended by a physician, is increasing and the relapse rate has not declined Although treatment with modern drugs brings about recovery without complications in 80 to 85% of patients, the cause of failure in the remaining 15 to 20% presents an urgent problem The speaker blamed home-care schemes for most of the failures Another factor is mistaking nocardiosis, which does not respond to antituberculosis drugs, for tuberculosis

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

A More Direct Liquefaction of Bronchial Secretion by Aerosol Therapy E R Levine Dis Chest 31 155-168 (Feb) 1957 [Chicago]

Bronchial secretion often presents the most difficult problem in the management of bronchopulmonary disease It is necessary to eliminate this secretion in order to maintain a free airway, but irritation must be avoided Aerosol therapy has become an important aid in the liquefaction of viscous secretion The author evaluates 4 different classes of aerosols and shows that in bronchopulmonary disease an aerosol is needed that contains a liquid, a detergent, and a mucolytic chemical and that, moreover is nonirritating to a normal bronchus Aerosols containing enzymes are not advisable because their use entails risks After careful investigation an aerosol solution was prepared that is referred to as Aerosol Solution No 2 It contains 0 125% of the detergent Tergitol 08 (sodium 2-hexylethylsulfate) and 0 1% of potassium iodide in sterile water

This aerosol was administered to 96 patients with severe chronic or acute coughs and with thick tenacious, viscid, mucopurulent bronchial secretion One characteristic that all these had in common was a spasmodic type of cough that produced noticeable dyspnea and, in some cases, actual cyanosis In all of them, a wheeze was audible and rhonchi and sibilant rales were obvious in the chest before treatment had started All of these patient had previously received broad-spectrum antibiotics for from 5 days to 2 weeks Potassium iodide had been administered by mouth for from 3 to 4 weeks in 50% of the cases, with only a moderate amount of improvement Several types of nebulizers were used The routine was 4 treatment periods of one half hour each daily The volume of aerosol used daily varied from 12 to 25 cc Sixty of the 96 patients were over 40 years of age and 6 were children under 10 years of age Treatment was continued for from 1 week to 6 months Almost all claimed some improvement immediately after the first inhalation, but there was no objective evidence of decreased viscosity or ease of expectoration until approximately 24 hours after therapy was started At the end of the first week of therapy, the sputum was definitely more liquid, and it expectorated easily without spasms of coughing in all of the patients treated No irritation of mucous membranes or toxicity was noted Clinical results were excellent in 66 and good in 30 patients

The Climate Factor in Perennial Respiratory Allergy and Its Relation to House Dust Sensitivity D Ordman Internat Arch Allergy 9 129-145 (No 3-4) 1956 (In English) [Basel, Switzerland]

During studies on allergic patients in various parts of the Union of South Africa, the concept of climatic respiratory allergy' emerged It was found that some allergic patients who are in fairly good condition while they are inland show more or less severe allergic symptoms when they live in coastal regions Pollens, fungi, and other exogenic allergens could be excluded as causal factors in many of these patients, and it is suggested that the development of symptoms while the patients are in coastal regions is due to the combination of high temperature and high relative humidity The question is raised whether in patients with "climatic respiratory allergy the climate as such exerts a physiological effect or whether the combination of high temperature and high relative humidity renders potential sensitizing substances, such as house dust, more highly allergenic The allergenic potency of house dust collected at the coast was compared with that collected inland by the 'threshold-concentration" skin-testing method carried out on allergic patients Coastal house dust was shown to be more highly allergenic than inland house dust There are indications that patients in the group with 'climatic" respiratory allergy are benefited by desensitization with extracts of coastal house dust

Does Tuberculosis Protect Against Cancer? H Grosse Ztschr ges inn Med 12 25-30 (Jan 1) 1957 (In German) [Leipzig, Germany]

Earlier observers were under the impression that tuberculosis protected the patient against cancer, but later the concurrence of tuberculosis and of carcinoma of the lungs was observed with increasing frequency This was generally explained by the fact that, with better treatment, patients with tuberculosis more often reach the "cancer' age According to some investigators the death rate of tuberculous patients even today is still 4 5 times higher than that of the general population Thus malignant tumors should be only about one-fourth as frequent in autopsies on tuberculous patients as in controls of the same age The 34,650 autopsy reports studied by the author revealed 3,115 cases of active tuberculosis and 7,511 cases of malignant tumors, 212 of the malignant tumors, including 58 pulmonary cancers, occurred in the patients with active tuberculosis

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals Requests for periodicals should be addressed Library, American Medical Association Periodical files cover 1948 to date only and no photoduplication services are available No charge is made to members but the fee for others is 15 cents in stamps for each item Only three periodicals may be borrowed at one time, and they must not be kept longer than five days Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them

Further analysis of these autopsy reports revealed that the incidence of cancer in men without tuberculosis was 24% and in those with tuberculosis 12.5%, and for women the corresponding percentages were 25 and 9. These figures, however, do not prove a negative syntropy of cancer and tuberculosis. On the contrary, since cancers occurred only from 2 to 2.8 times less frequently rather than 4 times less frequently, there seems to be a latent positive syntropy between the two diseases. Thoracic malignant tumors concur with tuberculosis more frequently than do extrathoracic tumors, especially in men. Thus it seems that the local predispotion to malignat tumors is much more definitely influenced by tuberculosis than is the general predisposition to malignant tumors. The author concludes that tuberculosis and other infectious diseases do not protect a patient against cancer, the apparent protection is explained by earlier deaths.

Investigations on Connections Between Acquired Hemolytic Anemias, Classical Blood Groups, Rhesus Factor, Sex, and Age. V. B. Lal and P. Speiser. Blut 3:15-19 (Jan.) 1957 (In German) [Munich, Germany]

Ninety-seven patients with acquired hemolytic anemia verified serologically were studied with regard to the distribution of blood groups, Rh$_0$ factor, sex, age, and several serologic data. There were no great differences between the distributions in these 97 patients and the corresponding distributions in 10,000 persons in the general population that would indicate a dependence of acquired hemolytic anemias on the hereditary serologic characteristics ABO, Rh$_0$, or sex. Clemens and Walsh had found in 1955 that, of 66 patients with acquired hemolytic anemia in Sydney, Australia, a much larger proportion were blood group O than could be expected from the blood-group distribution in the general population of Sydney. In the critical evaluation of this assumption the present authors gained the impression that if more exact mathematical rules are applied no correlation between blood group and acquired hemolytic anemia appears. Studies carried out by these authors likewise revealed no serologic differences between the idiopathic and symptomatic forms of this disease.

Cholelithiasis and Hypothyroidism. J. Warter and J.-P. Weill. Schweiz med Wchnschr 87:101-105 (Feb. 2) 1957 (In French) [Basel, Switzerland]

For several years the authors had noted that signs of hypothyroidism existed in patients in whom cholelithiasis appeared at an early age. They present observations on 15 patients with myxedema or simple hypothyroidism who had cholelithiasis. The existence of gall stones was verified either roentgenologically or by surgical intervention. Nine of the patients had hepatic colic, 3 had slight jaundice and mild pains, and in the other 3 the condition was discovered when cholecystography was carried out because of hypothyroidism. Those with thyroid insufficiency presented varied findings, such as cutaneous signs, a typical facial expression, and mental slowness. The metabolic rate was less than —12 in 5 of the patients and between —2 and —8 in the other 10. The blood cholesterol level was ascertained in 12 of the patients. It was between 1.5 and 2 Gm. per 100 cc. in 3 of the patients, and between 2 and 2.75 Gm. in the other 9. The fixation of radioactive iodine was investigated in only 2 of the patients, and it was low in both of them. It is significant that 8 of the patients were between 20 and 40 years of age, whereas cholelithiasis is generally regarded as occurring later in life. The fact that the group included 3 young men is likewise significant. The 15 patients were observed in the course of 7 years, and in this same period 60 patients with hypothyroidism were observed, that is, 15 of 60 or 25% of patients with hypothyroidism had cholelithiasis. The 60 patients with hypothyroidism included 15 with definite myxedema and of these 5 (33%) had cholelithiasis.

Hypothyroidism is regarded as the primary condition. Disturbances in the evacuation of the gallbladder, in the metabolism of cholesterol, and in hepatic function and endocrine disturbances have been mentioned as possible pathogenic factors. The authors believe that hypotonia of the gallbladder, disturbances in the metabolism of cholesterol and of the bile salts, and the influence of hormonal regulation represent a constellation of factors that would favor the concurrence of cholelithiasis with hypothyroidism. Diagnostic errors will be avoided if cholecystography is performed whenever digestive disturbances appear in patients with hyperthyroidism or myxedema. With regard to therapy, the authors suggest that thyroxin might be used as an adjuvant in cholelithiasis and as a prophylactic in hypothyroid patients, in subjects with a hereditary predisposition to cholelithiasis, or in patients who have been subjected to cholecystostomy.

Prognosis of Chronic Renal Failure 25 Years Ago and To-Day. P. Effersøe. Acta med scandinav 156:449-454 (No. 6) 1957 (In English) [Stockholm]

Of 12 patients with chronic disease of the kidneys in the terminal phase (i. e., with a renal function below 20% for more than 6 months) who were reported on by Van Slyke and co-workers in 1930, 10 died within an observation period up to 67 months. Half of them died after 9 months. These data were compared with those in a series of 37 patients with chronic disease of the kidneys in the terminal phase who were followed up for a similar period of time between 1949 and 1955. Of the 37 patients, 18 died, and half of them were dead after 13 months. Of Van Slyke's patients half had died after having had less than 10% renal function for 4 months. Of the author's patients half had died after having had the same degree of renal impairment for 8 months. At the end of the observation period, only 2 of the 12 patients were alive as compared to 19 of the 37 patients. Of the 19 patients with less than 20% renal function, so far 7 have survived for 6 to 12 months, 6 for 12 to 18 months, and 6 for an average of 22 months. A comparison between the conditions 25 years ago and today, thus, shows that the survival time of patients with chronic renal disease in the terminal phase who died, the survival time of the living, and the ratio of those living at the end of the observation period, all argue in favor of a better prognosis today than 25 years ago It cannot be said whether the improved prognosis in these patients is due to the introduction of antibiotics, more extensive use of blood transfusions, improved electrolyte regulation, or better dietetic treatment

Test of Adrenal Cortical Function by Administration of Corticotropin (ACTH) W Appel Ärztl Wchnschr 12 156-159 (Feb 15) 1957 (In German) [Berlin]

The 17-hydroxycorticoid excretion in the urine of 6 patients with adrenal cortical hypofunction before and after the administration of corticotropin was compared with that in 40 persons with normal function of the adrenal cortex Forty units of a repository preparation of corticotropin were given intramuscularly, and the urine was collected in 8-hour samples for 32 or 56 hours Determination of the corticoid values in the urine was made according to Reddy s technique modified by Forsham The excretion of the 17-hydroxycorticoids in the 24-hour urine specimens of patients with adrenal cortical hypofunction before the administration of corticotropin often did not differ from that of normal persons The basic excretion of 17-hydrocorticoids, therefore, is not sufficient to exclude the presence of adrenal cortical hypofunction After the stimulation of the adrenal cortex by the administration of corticotropin, the values of the 17-hydroxycorticoid excretion in normal persons and in patients with adrenal cortical hypofunction were found to be outside the simple range of variation of both groups Reduced amounts of 17-hydroxycorticoids were detected in the urine of the patients with adrenal cortical hypofunction Repeated administration of the corticotropin the next day did not cause an increase in the values of hydroxycorticoid excretion above 10 mg per 24 hours in the patients with adrenal cortical hypofunction

In patients who have been treated with cortisone, hydrocortisone, prednisone, or prednisolone for prolonged periods before they are subjected to the corticotropin test, this test should be made on 2 successive days, because the hydroxycorticoid excretion values may be of the adrenal-cortical-hypofunction type on the 1st day because of temporary weakening of the adrenocortical function and may reach normal values only after the 2nd test Those who have been treated with cortisone previously should be given prednisone before the corticotropin test in order to prevent the influence of the decomposition products of the administered steroids on the hydroxycorticoid excretion in the urine

The corticotropin test was performed on several patients with various forms of hyperfunction of the adrenal cortex Results showed that hyperfunction of the adrenal cortex (Cushing s syndrome) as a result of adrenal hyperplasia may be suspected when the 17-hydroxycorticoid excretion in the urine increases after the administration of corticotropin to more than 40 mg per 24 hours Patients with diabetic mellitus and obese patients with Cushing s syndrome particularly responded to the corticotropin test with high values of 17-hydroxycorticoid excretion Excessive values of 17-hydroxycorticoid excretion up to 128 mg and of 17-ketosteroid excretion up to 107 mg in the 24-hour urine specimen after administration of corticotropin were observed in a patient with moonface and values of 25 mg for hydroxycorticoid excretion and 35 mg for 17-ketosteroid excretion before the administration of corticotropin A patient with a congenital adrenogenital syndrome treated for 2 months with daily doses of 100 mg of cortisone had urinary levels of 12 or 14 mg of 17-hydroxycorticoid and of 7 6 or 8 8 mg of 17-ketosteroid before the administration of corticotropin and urinary levels of 24 mg of 17-hydroxycorticoid and 20 mg of 17-ketosteroid on the 2nd day of administration of corticotropin The increase in the levels of 17-ketosteroid in this patient was much more pronounced than that in the levels of 17-hydroxycorticoids The reported data confirm the great value of the corticotropin test in the diagnosis of adrenal cortical hypofunction and in the etiological differentiation of the various forms of hyperfunction of the adrenal cortex

Periarteritis Nodosa Four Cases R Armas Cruz, J Harnecker, O Gazmuri and others Rev med Chile 84 525-538 (Oct) 1956 (In Spanish) [Santiago, Chile]

Periarteritis nodosa is a collagen disease characterized by arterial inflammation and fibrinoid degeneration It is associated with nodular skin lesions, involvement of the visceral disorders of micturition and changes of the chemical constitution of the urine The diagnosis is made by the presence of a febrile infection, accompanied by diffuse articular pain, acute abdominal disorders, renal disease with or without hypertension, and symptoms of polyneuritis Allergic angiitis should be ruled out As the disease progresses the arteries of the most important viscera become involved The pulmonary arteries are spared, unless pulmonary hypertension or other pulmonary complication are present Generally the disease follows a rapid course to a fatal end Improvement of some of the symptoms has been reported from the use of corticotropin or cortisone, but this did not control the neurological symptoms In several patients, recurrences occurred on discontinuation of hormone treatment and death occurred even if the patients had shown a favorable response to the treatment Better results are reported from the use of prednisone and prednisolone Four cases with typical symptoms are reported The 1st patient died of cardiorenal insufficiency and pleuropneumonia Autopsy showed involvement of the coronary, renal, pancreatic, intestinal, and subarachnoid arteries The 2nd patient died of arterial thrombosis and purpura Autopsy showed involvement of the heart, spleen, and kidneys The 3rd patient had an abdominal form of the disease with obstructive jaundice A biopsy specimen confirmed the diagnosis When last seen the patient was in a remission and was taking cortisone The 4th patient had pneumonia, a buccal abscess, suppurative sinusitis, and renal insufficiency Autopsy showed it was involvement of the coronary, renal, and testicular arteries

SURGERY

Complications After Operations for Esophageal Atresia N Urban Ztschr Kinderh 79 194-202 (No 2) 1957 (In German) [Berlin]

Fifteen of 70 children who were operated on for esophageal atresia could be followed up for long periods *Unfortunately the life expectancy is favorable* for only a certain percentage of these children, because in many the condition is inoperable and many have other deformities or die of aspiration pneumonia, which is a frequent complication of this operation Other complications impairing the function of the esophagus operated on because of atresia may develop slowly and become evident only after a long time The author lists the types of complications that may interfere with the oral intake of food, the further development of the esophagus, or may endanger the *life of the child Interference with the intake of food* by a stricture in the region of the anastomosis resulting from shrinkage at the site of suture was the most frequent of the late complications The food intake of these children becomes gradually more difficult Aspiration of small quantities of food may eventually produce an aspiration pneumonia The upper part of the esophagus may become dilated and even pouchlike, vomiting may increase, the pouch may spill over while the infant nurses or drinks, and, finally, the infant may retain a few swallows only when erect In *one patient with this complication bougienage proved* effective

Cicatricial distortion of the esophagus may result *also from scars in the region of the mediastinum* and the right lung, the esophagus may be pushed out of line, and diverticula may form These conditions may also interfere with drinking Suture insufficiency is the most dangerous of the late complications of operations for esophageal atresia, it threatens especially when the anastomosis is under tension, that is, if a large defect has to be bridged Fistulas or pseudodiverticula to the mediastinum or to the lung may form and may cause pleurisy or refractory pneumonia This complication caused 2 of the 4 deaths in this group of children Foreign bodies may become lodged in the esophagus and may hinder the passage of food

Experiences in Closed Surgical Correction of Interatrial Septal Defects A S Traisman and H S Traisman Quart Bull Northwestern Univ M School 31 49-57 (No 1) 1957 [Chicago]

The intracardiac location of interatrial septal defects has hampered attempts at closure Both hypothermia and extracorporeal circulation techniques have been developed, with the treatment of interatrial septal defects among their specific objectives, but, since these techniques are still risky and also require prolonged preparation, the closed techniques for repair of interatrial septal defects are still being used at the Children s Memorial Hospital in Chicago Three major closed methods for repairing interatrial septal defects are presented the Gross technique of attaching a rubber well to an incision in the lateral wall of the right atrium, the Sondergaard technique of introducing a constricting suture along the rim of the interatrial septal defect, and the Lam technique of using a double-pointed needle to introduce sutures through the interatrial sulcus into the anterior rim of the interatrial septal defect

In operations on 22 children, only the latter 2 closed methods were used No occasion arose in the author's experience in which the well technique could not be replaced by one of the other 2 shorter methods The Sondergaard method was used in 4 children and the Lam technique in 18 The Sondergaard technique was particularly applicable to small interatrial septal defects of the ostium secundum type In the larger interatrial septal defects of this type, it is usually advisable to introduce several interrupted sutures in order to approximate the anterior and posterior walls of the defect without seriously narrowing the chamber of the left atrium Of all the available techniques, the safest and most efficient method is that made possible by use of the double pointed needle popularized by Lam The author concludes that the closed methods leave a great deal to be desired and that some type of direct closure that can be done with accuracy and low mortality will probably supplant them

Oesophageal Reconstruction in Children Using Intrathoracic Colon C D Sherman Jr and D Waterston Arch Dis Childhood 32 11-16 (Feb) 1957 [London]

Sherman and Waterston used 2 methods for esophageal reconstruction in children The 1st was devised by Waterston and consists in transplantation of the transverse colon isoperistaltically into the left posterior part of the chest on a pedicle containing the left colic artery The operation was performed 1st on an infant with atresia of the esophagus without tracheoesophageal fistula The reconstruction required 4 operations, which were carried out over a period of about 9 months About a month after the 4th operation the infant s stomach ruptured through a diaphragmatic opening This hernia was repaired, and since then the child has continued to thrive and has developed normally He eats everything and has no difficulty in swallowing The method has the advantage of preserving intact the all important cardiac sphincter mechanism between the esophagus and the stomach Two other babies in whom this technique was used for esophageal reconstruction are now 4 and 5 years of age respectively, and are both thriving In a 4th child an attempt was made to combine stages 2 and 3 into one operation The colonic loop was pulled up too tightly into the neck, thereby bowstringing the supplying artery The colonic loop became gangrenous and the child died a few hours after operation

In the second method of reconstruction the ascending colon is transplanted isoperistaltically in the retrosternal position This method was developed by Sherman In infants with esophageal atresia of tracheoesophageal fistula, it is wise to delay reconstruction The cervical esophagus is brought out in the left side of the neck, and a gastrostomy is performed on the following day At a later date, esophageal reconstruction is performed A longitudinal incision extending to the xiphoid is made and the ascending colon mobi lized by cutting the lateral attachments The length of the ascending colon is estimated, and the collateral vascular supply evaluated by placing a bull-dog clamp on the ileocolic artery During the waiting period to ascertain whether the blood supply to the cecum is maintained, an appendectomy is performed The ileum is sectioned from 4 to 6 in proximal to the ileocecal valve This leaves a segment of ileum that can be anastomosed to the cervical esophagus if it proves necessary The transverse colon just to the left of the middle colic artery is sectioned, and, after the sectioning of the ileocolic vessels, the transplant can be swung to the neck, the blood supply then coming through the middle colic vessels The transplant is carried through the substernal tunnel, which is cleared by blunt dissection in the anterior mediastinum The reconstruction is terminated by end-to end anastomosis of the cecum or ileum to the cervical esophagus, by anastomosis of the lower end of the transplant into the anterior wall of the stomach, and by end-to end ileotransverse colostomy The gastrostomy opening is left in place and may heal spontaneously or may be closed at a later date

Studies of the colonic blood supply have shown that at times one or other of the above methods may be impracticable because of lack of collateral circulation Other possibilities include (1) use of the transverse colon with the blood supply based on the middle colic and right superior colic vessels, (2) use of the transverse colon with the blood supply based on the middle colic and right superior colic vessels, (3) use of transverse colon with the blood supply based on the middle colic artery and left superior colic artery, (4) use of the descending colon with the blood supply based on the middle colic artery, (5) use of the cecum and terminal ileum with the blood supply based on the ileocolic artery, and (6) various methods of using the jejunum and stomach Reconstruction of the esophagus by colon transplant is still in the developmental stage, but experience suggests that further trial and evaluation are worth while

Treatment of Portal Hypertension in Children P Sandblom and C Ekman Arch Dis Childhood 32 61-64 (Feb) 1957 [London]

Of 82 patients operated on because of hypertension, 33 were under 20 years of age Splenoportography and measurement of the intrasplenic pressure proved useful in the establishment of a preoperative diagnosis in children and adults The main indication for surgery was esophageal hemorrhage The purpose of treatment was to reduce portal hypertension and, thereby, the tendency to esophageal hemorrhage by the establishment of a shunt between the portal and the caval systems In childhood the block was most frequently extrahepatic, while intrahepatic block was usually seen in patients with hepatic cirrhosis between the ages of 40 and 60 years An anastomosis was made in 7 of 8 patients with intrahepatic block, in the 8th only splenectomy was possible Of the 7 patients 5 have been free of symptoms for from 1 to 7 years The other 2 died 3 and 2 years after the operation The patients with the extrahepatic block included 21 ranging in age from 2 to 20 years who previously had not undergone splenectomy Eighteen of these were subjected to splenorenal anastomosis with suture Nine of these remained symptom-free during a follow-up period of from 1 to 4 years, whereas hemorrhage recurred in the other 9 patients, 6 of whom died Hemorrhages recurred also in the 2 patients in whom splenorenal anastomosis was established with the aid of a Vitallium tube, and 1 of these died The 1 patient who was subjected to splenectomy also died

Of 17 patients who had previously undergone splenectomy, 4 were subjected to anastomosis of small vessels and 2 to portacaval anastomosis All 6 of these patients later had hemorrhage, and 2 of them died Direct attack on the esophageal varices, i e, intraesophageal division of varices or partial esophagogastrectomy gave more encouraging results, in that, of the 6 patients treated in this way, only 1 had a recurrence Of 2 patients treated by mediastinal tamponage, 1 died and the other remained symptom-free The 3 patients who were subjected to laparotomy or Talma's operation died Only 6 of the 17 patients were symptom-free 1 year later While the primary mortality rate was higher in the group with intrahepatic block, the tendency to recurrence was much higher in the group with extrahepatic block, especially in the subgroup of patients who had previously undergone splenectomy A comparison of the results of portacaval anastomosis and splenorenal anastomosis in the entire series revealed that, after portacaval anastomosis, all of the 26 patients who survived were free from recurrences, while 13 of 33 survivors after splenorenal anastomosis had recurrences The more favorable results of portacaval shunt can be explained by the fact that the lumen is larger, and, therefore, the operation involves less risk of occlusion than does splenorenal anastomosis

Total Adrenalectomy for Malignant Hypertension W Van T Hoff Quart J Med 26 149-160 (Jan) 1957 [Oxford, England]

If the presence of papilledema is taken as the criterion for the diagnosis of the malignant phase of hypertension, nearly 80% of the patients not treated die within a year of the diagnosis Although there is no good evidence that adrenocortical hormones play an initiating role in essential hypertension, they do play a part in the maintenance of normal, and probably also of raised, blood pressure Treatment of essential hypertension by partial adrenalectomy was first reported in 1934 by DeCourcy, who believed that the resulting improvement in 8 patients was due to removal of the adrenal medulla Since the advent of replacement therapy, complete removal of the adrenals has been carried out in many patients, but in nearly all of them the operation was combined with some form of sympathectomy, which makes it difficult to assess the value of adrenalectomy alone

The author studied the effect of adrenalectomy in 5 patients with malignant hypertension and good renal function All were men, aged from 26 to 57, and before operation they had a mean resting diastolic blood pressure of 130 mm Hg or more Four patients had blurring of vision, and all 5 had papilledema, retinal hemorrhages, and exudates One patient was admitted to hospital with hematuria None gave a history of angina pectoris or showed any evidence of left ventricular or congestive heart failure After adrenalectomy all the patients were maintained on cortisone alone They felt better, their headaches improved, and they were all allowed to return to work in 4 months Papilledema, hemorrhages, and exudates improved in all, but none showed a significant reduction in blood pressure When further attempts were made to lower the blood pressure by reducing either the cortisone dosage or the salt intake, the patients showed signs of hypoadrenalism before there was any reduction in blood pressure While all the patients derived symptomatic benefit from adrenalectomy, there was no evidence that their lives were prolonged

Observations on the Use of 5-Hydroxytryptamine in Surgery L Sala Arch sc med 81 534-540 (Dec) 1956 (In Italian) [Turin, Italy]

The administration of 5-hydroxytryptamine had a beneficial effect on 42 patients subjected to appendicectomy, 8 to gastroresection, 10 to hysterectomy, and 10 to cholecystectomy All operations were performed under general anesthesia after premedication with morphine and atropine A dose of from 5 to 10 mg of the drug was injected intravenously, and, after a few seconds during which the respiration and blood pressure were controlled, narcosis was induced with pentothal and then the gas was administered A 2nd dose of from 5 to 10 mg of the drug was given to patients subjected to longer operations Bleeding was reduced markedly The best results were obtained in patients subjected to cholecystectomy or hysterectomy The little blood that was lost was denser than the blood lost by patients to whom the drug had not been given

The Clinical Control of Red Cell Loss in Burns E Topley and D MacG Jackson J Clin Path 10 1-19 (Feb) 1957 [London]

The development of anemia in badly burned patients has been attributed to bleeding granulations, blood loss at operation, and an impaired rate of red blood cell formation Only recently has an unexplained internal disappearance of red blood cells been considered to play a major role This raises such questions as 'When does this destruction occur?," "How great is it?,' and 'How urgent is replacement?" The data presented were obtained in a series of 150 patients In 86 patients the erythrocyte volume was studied Discussing possible ways of assessing red blood cell loss, the authors admit that they are not sure that some degree of oligemia is harmful, conversely they are not sure that keeping the blood volume normal at the price of using more plasma and producing more edema is beneficial, but prevention of more than a 20% reduction in blood volume seems reasonable Control of the blood volume must depend on serial erythrocyte volume and hematocrit measurements, if temporary oligemia is to be prevented This is possible only in a unit that specializes in the treatment of burns Massive red blood cell loss occurs most often in patients with extensive burns who have a chance of survival, and the prevention of oligemia in these patients is most rewarding Routine blood transfusion and serial hemoglobin estimations are not indicated in patients with burns involving less than 10% of the body surface, especially in those with less than 2% of full-thickness skin loss In patients with from 10 to 20% total area burned (usually from 2 to 10% full-thickness skin loss), early blood transfusion is probably unnecessary, but serial hemoglobin estimations every 2 or 3 days are indicated until less than 2% full-thickness skin loss remains unhealed In patients with from 20 to 40% total area burned (usually 10 to 30% full-thickness skin loss) a blood transfusion equal to 20% of the patient's blood volume should be given in the first 12 hours and the hematocrit kept between 10 and 20% above normal for the patient's weight and height, assuming there is 0 to 10% red blood cell loss A further 20% should be given in the next 36 hours if indicated clinically by oliguria, cold extremities, cyanosis, hemoglobinuria, or more than 2% microcytes in the head of a stained blood film on admission Subsequently repeated hemoglobin tests are required In patients with over 40% total area burned (usually over 30% full-thickness skin loss) 20% of the patient's blood volume should be given in the first 12 hours and the hematocrit kept at normal for the patient's height and weight, assuming 20% red blood cell loss One should then be prepared to give a further blood transfusion equal to 20 to 60% of the patient s blood volume in the next 36 hours if indicated clinically These are the patients in whom serial blood volume estimations are most valuable, provided the practical errors of such determinations are appreciated Subsequently, repeated hemoglobin tests are required

Elective Resection of the Colon for Diverticulitis M K Bartlett and W V McDermott M Rec & Ann 51 329 331 (Feb) 1957 [Houston, Texas]

Elective one-stage resection of the sigmoid was performed on 43 (60%) of 71 patients with diverticulitis in the course of 3 years Indications for elective resection consisted of an established pattern of recurrent attacks of acute diverticulitis, continuing symptoms of residual inflammation or of some degree of obstruction, persistent bleeding, the presence of a fistula, persistent urinary symptoms, and the suspicion of carcinoma Two of the 43 patients died, 1 of peritonitis and 1 of a pulmonary embolus Four other patients had complications, such as sepsis of the wound in 2 and atelectasis and pericarditis in one each Three stage resection was performed on 28 of the 71 patients There were no operative deaths The choice of a preliminary transverse colostomy was made in all of these patients because of the presence of a large inflammatory mass, frequently associated with perforation and abscess formation Three patients died in the immediate postoperative period after a transverse colostomy for what proved to be acute diverticulitis and carcinoma of the sigmoid with perforation

Diverticulosis of the colon is a relatively common condition, the diagnosis being established by barium enema or at autopsy These diverticula are acquired lesions, usually multiple, and may occur anywhere in the intraperitoneal colon but are most common in the sigmoid The presence of an area of acute diverticulitis in the sigmoid produces the familiar clinical aspect of pain and tenderness in the lower part of the abdomen, nausea and vomiting, fever, and an elevated white blood cell count Muscle spasm may be present in varying degrees, and a mass may be felt either by abdominal or bimanual examination The acute attack may progress to perforation of an inflamed diverticulum The perforation may erupt into the free peritoneal cavity with the development of spreading peritonitis, or a localized abscess may form that may occasionally result in a fistula either externally or into an adjacent organ The morbidity associated with the major complications of diverticulitis and the prolonged hospitalization and invalidism attendant on multiple stage operations have provided the stimulus for a more aggressive attitude toward the use of elective one-stage resection of the involved portion of the colon to forestall such complications The inflamed area is usually of quite limited extent, even in a fairly acute phase of the disease, and even though diverticula may be present both above and below the inflammatory zone This makes possible a relatively easy resection with normal intestinal wall available for suture both above and below the resected segment The process seldom extends down to the pelvic floor and is usually confined to the free sigmoid loops The operation is not without danger, and every effort must be made to be sure that the estimated risk of the disease is greater than that of the proposed treatment

GYNECOLOGY & OBSTETRICS

A New Factor in Maternal Mortality H B Turner J Kentucky M A 55 133-136 (Feb) 1957 [Louisville, Ky]

Maternal deaths have declined 85% in the past 20 years The principal causes had been sepsis, toxemia, and hemorrhage Toxemia as obstetric killer is today in 1st place, but, while improvement is being made in one direction, a new difficulty appears from another Anesthesia is the new killer, ranking 5th among the causes of maternal death Data were collected from the state of Michigan for the years from 1950 to 1954 Thirty-four of the 515 maternal deaths were the direct or indirect result of anesthesia These data were compared with those of the city of Memphis, Tenn, where, during the period 1946-1955, of 79 maternal deaths, 11 were caused by anesthesia On the other hand, in the Baptist Memorial Hospital from 1947 to 1956, there were 22,086 live births Of 11 maternal deaths in this series none were caused by anesthesia

In most of the cases, anesthesia was regional, saddle block being the most common In all instances, general anesthesia was induced by interns or residents giving nitrous oxide or ethylene for the spontaneous delivery of multiparas Laryngospasm occasionally occurs, and the danger of aspiration of vomitus is always present Efforts should be made to increase the number of well-trained anesthetists and to adequately distribute such personnel among all services requesting anesthesia Local anesthesia should be used in poor-risk cases and in situations in which regional methods are contraindicated Women have come to expect relief of the pains of childbirth Successful labor and delivery can, however, occur without maternal medication of any kind Few, if any, women ever died from the uncomplicated pains of childbirth

Poliomyelitis in Pregnancy A Report of 79 Cases in Connecticut M E Rindge New England J Med 256 281-285 (Feb 14) 1957 [Boston]

During the 5-year period 1951-1955, a total of 2,167 cases of poliomyelitis were reported to the Connecticut State Department of Health Males predominated in the age groups under 15 and females in the age groups over 15 years Females 15 years of age or over accounted for 456 of the cases reported, and, of these, 79 or 17 3% were known to have been pregnant when they became ill This is much higher than the estimate given by Weinstein, Aycock, and Feemster that 7% of women aged from 20 to 40 years are pregnant at any given time, and agrees with the accepted idea that pregnant women are more susceptible than nonpregnant women to poliomyelitis The danger of contracting poliomyelitis is apparently greatest in the 2nd trimester of pregnancy, the danger of loss of the fetus greatest in the 1st, and the danger of maternal mortality in the 3rd trimester The Connecticut figures support the theory that there is a tendency for poliomyelitis to occur in the 1st trimester of pregnancy in women who are carrying a male fetus and in the 3rd trimester in those carrying a female fetus as well as the theory that some factor related to household contact with children or associated with the presence of children in the household may account for the increased incidence of poliomyelitis observed in pregnant women It was also observed again that poliomyelitis in pregnancy, particularly in the early months of pregnancy, may lead to a general retardation in development of the infant

DERMATOLOGY

Fractionation of 17-Ketosteroids in Patients with Exfoliative Dermatitis Following Long-Term Cortisone Therapy T Putkonen, S Pesonen, K Rehtijarvi and R Kristoffersson Acta dermat -venereol 36 450-463 (No 6) 1956 (In English) [Stockholm]

Corticotropin secretion and adrenocortical function are reduced during the prolonged administration of cortisone in patients with certain skin diseases The authors studied the sudden interruption of hormone therapy in 3 men with chronic generalized exfoliative dermatitis who had been treated with cortisone, corticotropin, and hydrocortisone for 27 months, 26 months, and 11 months respectively They had taken hydrocortisone only for the last 5 or 6 of these months Fractionated determination of the 17-ketosteroids was carried out immediately before, during, and after the treatment-free period The interruption of treatment was best tolerated by a 44-year-old man, whose maintenance dose was only 60 mg of hydrocortisone, whereas, in the other 2 (aged 54 and 29 years), whose maintenance doses were 120 and 220 mg., respectively, there was severe oozing of the skin lesions, loss of weight, and a decline in the plasma proteins. During hydrocortisone therapy the urinary excretion of 17-ketosteroids and of dehydroepiandrosterone was low in all 3 patients. Immediately after the suspension of treatment, the excretion of 17-ketosteroids increased gradually, but later it declined again.

The most rapid and greatest increase was observed in the patient with the lowest maintenance dose. He also showed the greatest increase in the excretion of the dehydroepiandrosterone originating in the adrenal cortex, indicating that his adrenocortical function improved most. The patient with the largest maintenance dose (the 29-year-old man) likewise showed an increased excretion of dehydroepiandrosterone during the suspension of treatment, but no increase was seen in the 54-year-old man, who showed the least tolerance for the cessation of hormone treatment presumably because the adrenocortical atrophy was farthest advanced in this patient. His excretion of metabolites of hydrocortisone (11-oxy-17-ketosteroids) also was much higher during treatment than during nontreatment, which was not the case in the other 2 patients. The excretion of 17-ketosteroids originating in the testes, namely androsterone and etiocholanolone, was low in all patients during hydrocortisone therapy. After discontinuation of hormone administration, the androsterone excretion increased but that of etiocholanolone decreased, the combined level of the two thus remaining practically unchanged. These observations point to a functional insufficiency of both the testes and the hypophysis.

Histology and Cytochemistry of Human Skin: X-Irradiation of the Scalp. W. Montagna and H. B. Chase. Am. J. Anat. 99:415-445 (Nov.) 1956 [Philadelphia].

This report is concerned with changes that take place in the hair follicles during a period of 11 weeks after exposure to roentgen irradiation. Forty biopsy specimens of scalp were studied: 36 from white and Negro children from 5 to 9 years of age and 4 from adults. The responses to roentgen irradiation were identical in whites and Negroes and in the children and adults. The irradiation of hair follicles stops all mitosis in the cells of the matrix. These cells fragment and disappear during the 1st week. For 3 to 5 weeks after treatment, the lower half of each active follicle continues to degenerate, the hair drops out, and the entire follicle is reduced to a cord of cells. Damaged cells accumulate glycogen and lipid and lose their basophilia before they fragment. At the end of degeneration this cord is composed of the cells from the outer sheath in the upper half of the follicle and is comparable to a normal, quiescent follicle. The lower half of the follicle is dispensable and transient, and the upper half is the permanent part; from this are formed future generations of hair follicles.

While the bulb is degenerating and retreating upward, its base is never detached from the dermal papilla. During this time the dermal papilla loses its metachromasia, its stainability with the periodic acid–Schiff stain and its alkaline phosphatase activity. These properties are regained after 10 or 11 weeks, when the follicles are again growing normally. During the early period of follicle degeneration the cells of the dermal papilla engulf the melanin, lipids, and glycogen that are released by the degenerating cells of the bulb. These substances disappear after 4 weeks when large scale degeneration of the follicle has ceased. The dermal papilla, then, not only contains inductive substances that guide the growth and differentiation of hair follicles, but its cells also act as phagocytes. The vitreous membrane is a sensitive index of damage to hair follicles. Shortly after exposure to roentgen rays, it becomes thick and wrinkled and attains its maximum thickness after about 1 week. It remains very thick for 5 to 7 weeks until the follicle again becomes active. The membrane then becomes fragmented.

OPHTHALMOLOGY

Autokeratoplasty: Covering of Donor-Site with Lyophilized Human Cornea. B. Alberth. Ophthalmologica 133:61-64 (Jan.) 1957 (In German) [Basel, Switzerland].

Autoplasty is the best solution for corneal transplantation, because the transparency of the transplant is not impaired by immunobiological processes. Several procedures are available for the disk-shaped autokeratoplasty. Transplantation of a disk of the clear cornea of a blind eye to the opacity of the other eye was performed in the 69-year-old patient whose history is presented. After a transparent corneal disk from the right, blind eye had been transplanted to the leukoma in the left eye, the defect of the donor site was covered by a slice of cornea obtained from a lyophilized human cornea. The authors had waited for an opportunity to use such material, and they believed that since the donor eye to be grafted was blind, the method could be tried. A human eye that had been preserved by the "adsorptive lyophilization" method of Bornemissza-Szilagyi and that had been kept in a sterile tube at room temperature for 152 days was taken out 30 minutes before the operation and was regenerated in isotonic sodium chloride solution at 37 C (98.6 F). A disk 5-mm in diameter was trephined out of this eye and was placed over the defect in the right, blind eye of the patient. This corneal graft grew in but became cloudy, whereas the autotransplant remained transparent.

Neoplasms of the Notochord: Report of a Case of Basilar Chordoma with Nasal and Bilateral Orbital Involvement. C. D. Binkhorst, P. Schierbeek and G. J. W. Petten. Ophthalmologica 133:12-22 (Jan.) 1957 (In English) [Basel, Switzerland].

The notochord is a column of cells formed in the central axis, ventrally from the neural tube. In vertebrates it is a transitory organ, its supporting function being taken over by the vertebrae developing around it, but vestiges of chordal tissue may remain and in these chordomas may develop. A 70-year-old woman with this rare form of tumor was seen because of nasal obstruction and increasing frontal headaches Her friends had observed her protruding eyes and a "polyp' showing in her right nostril Twelve years previously she had completely lost her eyesight At that time tumor of the hypophysis had been diagnosed, and a tumor dose of 2,000 r had been applied Examination in 1955 revealed protrusion of both eyeballs with conspicuous lateral displacement Between the medial angles of the eyes and the ridge of the nose a tumor mass was apparent, and from the right nostril a glassy mass of tissue protruded Similar tissue was found in the left half of the nose, and the nasopharynx was also obstructed with it These and other findings and the course of the process suggest a slow-growing neoplasm causing destruction of the base of the skull with invasion into the facial part of the skull Intracranial growth had probably remained limited to the region of the optic chiasm The glassy appearance of the tumor suggested chordoma

In 3 sessions about 65 Gm of the tumor mass was removed by the endonasal route The patient felt much relieved after this, the patency of the nose was reestablished, and the headache disappeared Five weeks later the right frontal and ethmoidal sinuses were widely opened The floor of the frontal sinus and the frontal wall of the ethmoid proved to be missing Another 50 Gm of tissue was removed The histological examination of the tissue confirmed the diagnosis of chordoma The authors confine their discussion to chordomas originating in vestiges of the craniocervical notochord In this area 6 points of origin exist, but ectopic localizations have been described in the mandible and in the frontal sinus On studying the cases described in the literature, the authors found that the onset is fairly often characterized by a more or less typical neuroophthalmological syndrome, consisting of fronto-orbital headache, loss of visual acuity, limitation of the visual fields of 1 or both eyes, respectively, and paresis of the eye muscles In cases of extracranial growth exophthalmos may occur, coupled with an early invasion into the nasal sinuses and the nasopharynx The clinical differentiation from other tumors of the base of the skull may be difficult, particularly with respect to subtentorial foci, tumors of the pontine angle, tumors originating in the paranasal sinuses and the nasopharyx, and disorders near the optic chiasm An important point in the differential diagnosis is the fact that basilar chordomas, with their strong tendency to extracranial growth, give rise to intracranial complications only at a late stage The growth of a chordoma is nearly always slow, but, with respect to bone, it is particularly destructive Therapy is usually palliative

The Correction of Exophthalmos and Levator Spasm

R E Moran Plast & Reconstruct Surg 18 411-426 (Dec) 1956 [Baltimore]

Dimmed vision, total blindness, or even death occurred in patients with malignant exophthalmos as late as 1931, when Naffziger relieved severe exophthalmos by decompression of the orbital contents into the anterior cranial fossa While orbital decompression was a distinct advance, Naffziger's operation was a formidable one and a less radical approach seemed desirable Dollinger in 1911 had used lateral decompression of the orbit successfully in a patient with malignant exophthalmos, and others had described techniques for decompression into the sinuses The author together with the late Dr Shugrue carried out experiments in the anatomic laboratory with the hope of finding a safer approach for decompression in patients with symptoms not severe enough to warrant the use of the formidable Naffziger technique They worked out a simple technique for removing the lateral orbital wall (without disturbing the orbital rim), and opening the orbital fascia to permit decompression of its contents into the temporal and infratemporal fossae

The author described this operation in 1937, and he has used it so far in 33 patients Ten were under 30 years of age, 12 were between 30 and 40, and 11 were over 40 Decompression through the lateral wall of the orbit was performed bilaterally in 20 of the patients There were 55 decompression operations on the 33 patients, with no deaths In patients in whom the exophthalmos was stationary and levator spasm was absent at the time of operation, the drop in exophthalmos was more rapid and more striking than in those in whom the levator spasm was a postoperative factor and active disease was present in the orbit (as evidenced by conjunctival edema, etc, at the time of operation) In the former patients, the average drop in exophthalmos readings was 6 mm, whereas in the latter, the average drop was under 5 mm When no levator spasm existed after decompression, the ocular muscles regained their tone more quickly, particularly in those with paresis of the superior rectus muscle The edema and conjunctival irritation subsided more quickly when levator spasm was present When levator spasm was marked in only 1 eye, the exophthalmos was usually more pronounced on that side The levators were operated on as an adjunct to decompression in 12 patients and, bilaterally, in 9 patients In 3 patients with unequal exophthalmos, only 1 eye was operated on In 2 patients with unilateral exophthalmos, the levator was surgically weakened and no decompression was necessary Because of a residual elevation of the temporal side of the lid, the first 4 patients were reoperated on with satisfactory results

THERAPEUTICS

On the Use of Salts of Rare Earth Metals (Neodymium Combined with Praseodymium) for Prophylaxis of Thrombosis

W Osten Ärztl Wchnschr 12 107-112 (Feb 1) 1957 (In German) [Berlin]

A series of 46 selected surgical patients was studied Because of their constitution, the condition of their circulation, their age, and the operative trauma, they were considered to be threatened by thrombosis and were treated prophylactically with a 1% solution of a compound (Helodym 88) containing 65 to 70% of the neodymium salt and of 35 to 30% of the praseodymium salt of beta-acetylpropionic acid The recommended initial dose for a patient weighing 154 lb (70 kg) with a normal (100%) thromboplastin time is 7 cc, that for a patient with a thromboplastin time of 80% of normal 5 6 cc , and that for a patient with a thromboplastin time of 120% of normal 8 4 cc of the 1% solution of Helodym 88 Additional doses depend on the values of prothrombin and proconvertin A reduction to from 50 to 30% of the normal may be sufficient for prophylactic purposes Slow intravenous administration appeared to prevent side-effects Except in patients who underwent operations on the stomach, intestine, and thyroid and those who were subjected to operations associated with great loss of blood treatment was started from 6 to 10 hours after the operation or even before the operation In the exceptional patients, treatment was started on the evening of the day of operation or on the morning of the 1st postoperative day Treatment was continued for from 4 to 10 days The duration of treatment is longer in older than in younger patients because of a greater tendency to develop thrombosis and longer postoperative rest in bed Treatment should be discontinued gradually within 1 or 2 days, with reduced doses Dose and duration of the treatment as given represent a general guide, but they must be adapted to the individual need depending on the tendency to bleed or clot Treatment with Helodym 88 is contraindicated after neurosurgical operations, during pregnancy and menstruation, and in patients with a particular tendency to bleeding

Thromboembolic accidents did not occur in any of the 46 patients who were treated with Helodym 88 The drug inactivates the prothrombin and proconvertin circulating in the blood by forming a complex of α_2-globulin (i e , prothrombin plus proconvertin) with the rare earth metals The effect of Helodym 88 can not be counteracted by giving vitamin K_1 Prolonged treatment with Helodym 88 causes blockade of the synthesis of prothrombin and proconvertin in the liver Impairment of the hepatic parenchyma that was present before starting Helodym 88 treatment may become worse as a result of the treatment The patients should be placed on a diet free of oxalates (rhubarb, gooseberries) to prevent renal damage in the course of the treatment with Helodym 88

The Anticoagulant Effect of a New Coumarin Derivative—Sintrom (Geigy)—and Its Control by Standardized Clotting Time G A Mayer and W F Connell Canad M A J 76 272-278 (Feb 15) 1957 [Toronto]

Anticoagulant treatment with Sintrom, a new coumarin derivative, was given to 42 patients, 22 of whom had acute myocardial infarction, 12 acute coronary insufficiency, 3 pulmonary embolism, 4 peripheral thrombophlebitis, and 1 cerebral embolism The patients were studied for a period of 866 treatment days On 18 of these days heparin only was administered, for 128 days heparin and Sintrom were given concurrently, and for 720 days Sintrom was given alone Sintrom was started on the 1st day with a dose of from 20 to 24 mg On each of the following 3 days the dose was reduced by 4 mg , the total dose for the day being given at noon after food Control of anticoagulant treatment was maintained with the aid of the standardized clotting time measured in unmodified venous blood immediately after withdrawal according to Mayer s method described in THE JOURNAL (161 806 [June 30] 1956)

The therapeutic aim, to keep the standardized clotting time between 15 and 20 minutes, was achieved in 71% of treatment days when Sintrom was the sole anticoagulant used On 15% of treatment days the standardized clotting time was less than 15 minutes, on 12% it was between 21 and 25 minutes, and on 2% between 26 and 30 minutes Sintrom produced a therapeutic prolongation of the standardized clotting time after an average induction period of 4 3 days No hemorrhagic accidents or thromboembolic complications were noted when the standardized clotting time was maintained within the authors desired range When treatment with Sintrom was discontinued, the standardized clotting time returned to its pretreatment level within from 48 to 72 hours Under the conditions of this study, Sintrom proved to be a satisfactory oral anticoagulant for short-term therapy Sintrom therapy was adequately and easily controlled with the aid of the standardized clotting time No significant correlation was found between the Quick one-stage prothrombin test and the standardized clotting time

Phenylbutazone Effects of Its Administration for Prolonged Periods W C Kuzell, R W Schaffarzick, W E Naugler and B M Champlin New England J Med 256 388-392 (Feb 28) 1957 [Boston]

Phenylbutazone was given for from 12 to 54 months to 34 men and 66 women with a variety of rheumatoid disorders, 73 of whom were in the 4th, 5th, and 6th decades of life Not a single patient was previously satisfied with the relief afforded by the salicylates All the patients initially had a favorable therapeutic response to phenylbutazone and freedom from untoward side-effects of the drug permitted its prolonged administration The range of the daily dose of phenylbutazone varied between 100 and 600 mg The usual daily dose was 300 or 400 mg When the drug was given intramuscularly the daily amount varied from 0 6 to 1 0 Gm for 2 or 3 days, followed by oral administration as described above

Of the 100 patients, 60 had rheumatoid arthritis, 23 ankylosing spondylitis, 4 psoriasis with arthritis, and 13 mixed arthritis (rheumatoid arthritis and degenerative joint disease) Of the 60 patients with rheumatoid arthritis who received phenylbutazone for 54,180 patient-days, 53 had an initial grade 1 or 2 therapeutic response in accordance with the criteria of the American Rheumatic Association In 46 of these 53 the favorable response was maintained for the duration of the treatment All of 7 with a minor (grade 3) initial therapeutic response maintained the original degree of improvement None of these 7 patients progressed to grade 1 or 2 regardless of duration of the treatment Only 4 of the 60 patients discontinued treatment, 3 for various reasons, and the 4th died of hemorrhage from a duodenal ulcer while taking phenylbutazone and hydrocortisone concurrently All the 23 patients with ankylosing spondylitis who received phenylbutazone for 16,650 patient-days obtained initial major improvement that was maintained throughout the period of treatment Two discontinued treatment, 1 because of nervousness and 1 because of peptic ulcer The 4 patients with psoriasis and arthritis received the drug for 680 patient-days and had major improvement The 13 patients with mixed arthritis received phenylbutazone for 9,360 patient-days, 11 achieved a major therapeutic response, which was maintained in 9 One of 2 who obtained only minor improvement continued to be improved at the end of the study

One woman with rheumatoid arthritis had agranulocytosis after a severe upper respiratory infection after 16 months of treatment with the drug Agranulocytosis occurred in another woman with mixed arthritis who had received phenylbutazone for 28 days and acetosulfone for 21 days concurrently Both these women later were successfully treated with phenylbutazone for many months Laboratory examinations performed on 50 of the 100 patients at the end of the study gave no evidence of hematological or hepatic damage attributable to prolonged treatment with phenylbutazone The abnormalities in these laboratory determinations were those habitually found in patients with these rheumatic disorders In 90 of the 100 patients, the original favorable response was maintained Although phenylbutazone was occasionally withheld temporarily because of untoward side-effects, its administration was resumed successfully in all but 6 patients As a rule, in patients with ankylosing spondylitis a greater degree of favorable therapeutic response was achieved and afterward maintained with a smaller daily dose than those with rheumatoid arthritis, mixed arthritis, and psoriasis with arthritis

PATHOLOGY

Relationship Between Renal Function and Clinical Course in Chronic Renal Failure Based on 29 Autopsied Cases P Effersøe Acta med scandinav 156 435-448 (No 6) 1957 (In English) [Stockholm]

The relationship between the clinical course and the results of the endogenous 24-hour creatinine-clearance test, used as renal function test at a general hospital, was studied in 29 patients with chronic disease of the kidneys The patients were selected on the basis of autopsy findings without regard to the results of renal function tests made while they were still alive Patients with other diseases that might have influenced the chronic nephropathy, particularly those with cancer, were excluded Of the 29 patients, 6 between the ages of 33 and 69 years had congenital cystic disease of the kidneys and 23 between the ages of 18 and 73 had kidneys of half the normal size as determined by autopsy The 29 patients had been tested and treated at the hospital or had been followed up as outpatients for several years before their deaths Patients with severe cardiovascular signs, such as pronounced cardiac edema, pulmonary edema, encephalopathy, or apoplexy, or patients with purulent urine had a serum concentration of creatinine at the time of their deaths that was much lower than that of the patients who did not present such cardiovascular signs or did not have pus in the urine at the time of their deaths The serum concentration of creatinine also varied greatly in the patients with cardiovascular complications or pus in the urine This finding suggests that the renal function has no direct influence on the fatal issue

The patients without such cardiovascular signs and those who did not have pus in the urine showed only 1 common feature concerning the renal function in the course of their illness, namely a further impairment of the function from about 5% to about 4% of the normal as revealed by a rise in serum creatinine level from 9 to 13 mg per 100 cc to 14 to 16 mg per 100 cc within the period from 6 to 3 months before their deaths The patients will survive for from 3 to 6 months after their impairment in renal function has taken place, no matter whether the impairment progresses still further after the 4% level has been reached The patients whose renal function exceeds 5% of the normal as measured by the endogenous 24-hour creatinine clearance test (a serum creatinine level below 11 mg per 100 cc) can survive for several years, and the prognosis remains uncertain until the renal function drops below 5% This applies to patients with cystic kidneys and chronic pyelonephritis No correlation was found between the serum urea concentration at any time in the course of the disease and at the time of death

Discrimination Between Obstructive and Hepatocellular Jaundice by Means of the Commonly Used Serum Tests E Hill and L Zieve Am J Clin Path 27 6-12 (Jan) 1957 [Baltimore]

The comparative effectiveness, separately and in combination, of 5 commonly used serum tests was evaluated in an unselected, consecutively observed group of 49 patients with obstructive jaundice who were paired individually, on the basis of the degree of bilirubinemia, with a group of 49 patients with hepatocellular jaundice Nineteen additional patients were excluded from the study because 1 or more of the 5 hepatic tests to be evaluated were lacking Carcinoma was the cause of obstruction in 28, stones in the common bile duct in 14, pancreatitis in 5, stricture of the common duct in 1, and the cause was unknown in 1 patient Of the patients with hepatocellular jaundice, 24 had viral hepatitis and 25 had cirrhosis

Tests used were those generally available in the ordinary clinical laboratory cephalin-cholesterol flocculation, thymol turbidity, zinc sulfate turbidity, alkaline phosphatase expressed in King-Armstrong units, and the serum cholesterol level Cephalin-cholesterol flocculation was by far the most discriminating test The thymol turbidity test was 67% as effective, the alkaline phosphatase and zinc turbidity tests were 50% as effective, and the serum cholesterol level was 40% as effective A combination of all 5 tests was only slightly better than the cephalin-cholesterol flocculation test alone It is recommended that primary reliance be placed on the cephalin-cholesterol flocculation test and that corroborative information be sought with the alkaline phosphatase and thymol turbidity tests

Changes in the Pituitary Gland in Massive Therapy with Steroids T R Cox and W Krohn Am J Clin Path 27 24-28 (Jan) 1957 [Baltimore]

The recent innovation of treating leukemia with massive doses of steroids prompted the authors to study the pituitaries of such patients and compare them with those of patients who had received small maintenance doses of steroids The 12 patients whose pituitaries were studied had received prednisolone, hydrocortisone, corticotropin, or cortisone in large daily doses Prednisolone, for example, was given in daily doses up to 5 Gm (usually 3 Gm) Many of the patients had received total doses of over 27 Gm The pituitaries were studied in routine hematoxylin-eosin preparations and by a modified periodic acid-Schiff, orange-G, aniline blue stain for pituitary granules This stain clearly reveals the 4 types of pituitary cells acidophilic, chromophobic, periodic acid–Schiff positive, and periodic acid–Schiff negative basophilic All of the patients had had acute or chronic leukemia Examination of the hematoxylin-eosin–stained slides proved surprisingly disappointing Hydropic and hyalinizing changes were found in only a small number of the cases Varying amounts of atrophy and apparent fibrosis, particularly in the region of basophilic cell localization, were rather constant features It was not until the granule stains were studied that a pattern revealed itself The cases were broken down into 3 groups on the basis of amount of periodic acid–Schiff activity because a striking variation in the number of positive cells was noted

In the pituitaries of patients in group 1 who had received 27 Gm of steroids or more a striking increase in periodic acid–Schiff activity and diminished numbers of basophils that are periodic acid-Schiff negative were consistent features Studies now in progress show a moderate decrease in protein-bound iodine and decreased radioactive iodine uptake after massive steroid therapy Inasmuch as these cells that are periodic acid–Schiff positive are believed to be responsible for thyrotropic hormone and their number is found to be increased in the absence of the gland, one might wonder whether these large doses had directly suppressed the thyroid gland, bringing about increased thyrotropic activity in the pituitary Loss of the basophils that are periodic acid–Schiff negative, in some instances, seemed to be due to loss of specific granules from the cells and, in other instances, to an actual degenerative process The changes in groups 2 and 3 corresponded closely to the ages of the patients and to gonadal function

RADIOLOGY

Irradiation Therapy in Brain Tumors W Hellriegel Strahlentherapie 102 21-30 (No 1) 1957 (In German) [Munich, Germany]

In a series of 248 brain tumors treated by irradiation pituitary adenomas accounted for 79, glioblastomas for 71, astrocytomas for 21, and medulloblastomas for 15 Spongioblastomas, oligodendrogliomas, ependynomas, neurinomas, meningiomas, angioblastomas, craniopharyngiomas, and others were represented in smaller numbers In the treatment of brain tumors the radiologist must collaborate with the neurosurgeon, who plays the leading role About half of the pituitary tumors could be improved by irradiation With properly aimed irradiation, such as the convergence method, improvement can be achieved in 67% of the patients In the other types of brain tumors the author prefers the pendulum or oscillating type of irradiation The stationary-field type of irradiation is used only on patients with superficial tumors Commenting on the interstitial implantation of radioactive isotopes, the author says that at his clinic grains of radioactive gold are implanted Either the bed of the tumor is implanted with these radioactive grains during the operation, or the gold is implanted by the transcutaneous route after most of the tumor has been resected A tumor dose of 6,000 r gives the best survival rates, this was especially evident in the 71 patients in whom irradiation was used for glioblastoma, 5 of whom survived for 5 years or longer

Thorotrast Disease L Fruhling, C-M Gros, A Batzenschlager and M Dorner Ann med 57 297-350 (July-Aug) and 57 409-486 (Sept-Oct) 1956 (In French) [Paris]

The excellent contrasts obtainable with Thorotrast (a colloidal suspension of thorium dioxide) caused it to be widely used in radiologic practice for some 10 years after its introduction about 1930 Reports of late complications, steadily increasing in number and severity, then began to appear and it soon became clear that the entire question of using Thorotrast would have to be reviewed in the light of these late effects This the authors have attempted to do, devoting the 1st part of their study to a general consideration of the physical characteristics of Thorotrast, its history, its clinical use, and the experimental findings Part 2 deals with the microscopic identification of Thorotrast and the histopathology of the late lesions, whatever their character or location Part 3 is a report on the anatomic and clinical findings in 21 patients with late lesions due to the injection of Thorotrast for which the authors use the general term Thorotrast disease

Their findings make it clear that the introduction of Thorotrast into the body is constantly followed by late lesions, which may appear as (1) a local thorotrastoma causing only local symptoms, (2) a local thorotrastoma *accompanied by clinical signs related to a generalized* Thorotrast infiltration, (3) generalized Thorotrast infiltration with clinical manifestations but without a local thorotrastoma, (4) generalized Thorotrast infiltration discovered accidentally at autopsy, and (5) cancer associated with lesions due to Thorotrast Thorotrastomas, which develop whenever a quantity of Thorotrast is injected into the connective or celluloadipose tissue either intentionally or by accident, are inflammatory pseudotumors The injected Thorotrast, acting as a foreign body, is phagocytized by reticulum cells—histiocytes or macrophages These cells eventually undergo necrosis, setting the grains of Thorotrast free to reexert their irritating action The resulting sclerosis is intensified with each repetition of the process, and, since virtually none of the Thorotrast is ever eliminated, the lesions progress slowly but inexorably

Thorotrast, however, is not merely an inert foreign body, it is also a practically inexhaustible source of radioactivity—emitting alpha, beta, and gamma rays, and certain forms of cellular necrosis should undoubtedly be attributed to this fact The severity of the late lesions due to Thorotrast is linked to the development of diffuse sclerosis of the liver resulting in irregular cirrhosis and severe degenerative changes in the liver structure Involvement of the bone marrow is clearly evident on histological study, clinically, it is shown by moderate anemia, sometimes accompanied by platelet deficiency and mild leukopenia The indications are that Thorotrast favors the appearance of cancer, especially endothelial sarcomas of the liver and the spleen Cancers were found in association with thorotrastosis in 3 of the authors patients These findings show that the use of Thorotrast in human subjects should be absolutely forbidden

Osteogenic Sarcoma of the Skull Following Irradiation E M Skolnik, E J Fornatto and J Heydemann Ann Otol Rhin & Laryng 65 915-936 (Dec) 1956 [St Louis]

The authors present the histories of 2 patients with osteogenic sarcoma of the skull In the 1st patient, a 20-year-old man, the sarcoma developed in the temporal bone 3½ years after a postauricular keloid had been irradiated with a total of 6,050 r in air The sarcoma was resected In the 2nd patient, an 11-year-old girl, sarcoma developed in the frontal bone 10 years after the irradiation of a retinoblastoma (with radon seeds over a period of 9 months) and was inoperable Eight similar cases reported in the literature are reviewed The relatively young age of the patients, the minimum dosage of 3,000 r, the prolonged duration of irradiation treatment and a latent interval of at least 3 years are important factors in the development of osteogenic sarcomas of the skull from this cause These neoplasms are characterized by rapid growth Malignant degeneration should be suspected if a localized swelling or mass develops in a region of previous irradiation, particularly if associated with skin alterations, pain, and functional disturbances

Osteogenic sarcomas of the skull after irradiation have no specific radiologic feature The main characteristics are the presence of a soft tissue mass, bone destruction with cortical involvement, periosteal reaction and eventually complicating fractures Osteogenic sarcoma is a highly malignant neoplasm derived from cells analogous to osteoblasts Its essential feature is the formation of osteoid tissue directly by the malignant osteoblasts with no intermediate fibrous or cartilaginous matrix The presence of cartilage or giant cells does not exclude the diagnosis No definite histological characteristic could be demonstrated in the osteogenic sarcomas of the skull after irradiation Wide surgical resection appears to be the treatment of choice, but no definite conclusion is possible at present Prolonged irradiation of benign lesions should be avoided

PHYSIOLOGY

Investigations on Effect of Prethcamide (Micoren) on the Physiology of Respiration A Buhlmann and H Behn Schweiz med Wchnschr 87 135-137 (Feb 9) 1957 (In German) [Basel, Switzerland]

The authors emphasize the need for effective analeptics in the treatment of intoxications in which respiration is impaired They describe investigations on the new analeptic prethcamide (Micoren), a mixture of two alkylimino fatty acids, crotethamide and copropamide (see THE JOURNAL 155 363 [May 22] 1954) They tested its effect in 3 persons with practically normal arterial carbon dioxide tension, in 1 person with slightly increased tension, and in 11 patients with chronic respiratory acidosis resulting from obstructive emphysema in chronic asthmatic bronchitis or chronic bronchial asthma In a 12th patient the chronic alveolar hypoventilation was a sequela of severe obesity These 12 patients had a mild to moderate respiratory insufficiency with hypoxemia and hypercapnia They were selected because the irritability or activity of their respiratory center was higher than normal and in the hope that prethcamide would help them All subjects received by slow intravenous injection 3 cc of a 15% solution (450 mg) of prethcamide With the aid of a self-retaining cannula, arterial blood was obtained anaerobically before and 5, 10, and 15 minutes after the injection The blood was analyzed with regard to oxygen capacity, oxygen saturation, carbon dioxide content, and pH The carbon dioxide tension was computed on the basis of the carbon dioxide content of the plasma and the pH In order to obtain information about the respiratory mechanism and the ventilation, the esophageal pressure reading, the pneumotachogram, and the electroencephalogram were taken simultaneously with the withdrawal of the blood specimens

Prethcamide produced a decisive increase in the total ventilation and a noticeable increase in the alveolar ventilation, with corresponding improvement in the arterial carbon dioxide tension In the presence of pulmonary hypertension resulting from alveolar hypoventilation, a decrease in pressure, which corresponded to the improvement in the alveolar gas pressure resulted under the influence of prethcamide Otherwise, however, the drug had no significant circulatory effect, at least not with the dosage and mode of administration used Prethcamide had only slight secondary effects but it was a very effective respiratory stimulant and analeptic Its use is indicated particularly in patients with central respiratory disturbances such as in those resulting from poisoning with soporifics or morphine and in asphyxia of the new-born A reduction in the arterial carbon dioxide tension can be achieved in chronic respiratory acidosis resulting from obstructive emphysema Observations on the respiratory mechanism suggest that the drug is suitable for prolonged treatment only in combination with bron-

PUBLIC HEALTH

Effect of Food Preferences on Nutrient Intake C M Young and T D Lafortune J Am Dietet A 33 98-103 (Feb) 1957 [Chicago]

Dislike for certain foods becomes important, if it seriously interferes with the adequacy of a person's intake of food Such interference would occur only in those with many dislikes and particularly with dislike of certain key foods Excessive food dislikes frequently are associated with neurotic tendencies or with immaturity Women, particularly adolescent girls, are shown to have more food dislikes than men, and they are recognized to be 1 of the least well-fed groups in the population A study of the relationship between food dislikes and other factors leading to food rejection was made in a group of Cornell University freshmen women They were studied early in their freshman year while food preference still was under home influence, 145 were chosen at random and sent questionnaires Ninety responded and 81 completed all the necessary entries The ages of the girls were from 16 to 20, their heights from 60 to 70 in , and their weights from 100 to 169 lb About 54 came from small communities, the others from large urban areas The girls were asked to keep a record of all food and drink, except water, taken for 1 week Time and place should also be listed The menus served and the size of servings of the various foods were furnished by the dietitians

Fifty-two of the 185 food items (28%) included in the check list were not disliked by any of the girls Thirty-two of the 81 girls had dietary intakes below 70% of the recommended dietary allowances for 16-to-20-year-old girls in one or more nutrients Calcium, iron, and thiamine appeared to be the area of greatest weakness in nutrient intake 23 of the girls had calcium intakes below the 70% level, 21 had iron and 12 thiamine intakes below this level In general, religious food restriction did not influence the adequacy of the diet Health and caloric restrictions had an influence on 24 of the girls who were dieting to lose or gain weight Milk, eggs, bread and cereals were not used in the available quantities, yet the girls did not list them as disliked foods The authors explanation for these less-than-desirable food intakes is the indifference of the girls to certain of the available foods That eggs were an intensely disliked item on the check list is peculiar It is clear, however, from the responses to the oral questioning, that the real cause is definite individual preference with regard to the preparation, not a dislike of eggs

Food dislikes seemed to have little influence on the adequacy of the diet, because the most intensely disliked foods were listed among the 'seldom-served' or 'never-tasted' items The solution of the less-than-desirable nutrient intakes at least in this group would seem to be an educational program aimed not at combating food dislikes but rather at emphasizing the importance of certain foods, which appear as optional items on the menu This type of study should be extended to other population groups

INDUSTRIAL MEDICINE

The Danger of Dermatoses Due to Cold Setting Ethoxyline Resins (Epoxide Resins) E Grandjean Brit J Indust Med 14 1-4 (Jan) 1957 [London]

The ethoxyline and epoxide resins are used as adhesives and casting resins in the manufacture of various kinds of apparatus, electrical equipment, automobiles, and aircraft They are usually supplied in the form of 2 reactive components, resin and hardener The introduction of ethoxyline resins (under the trade marks of 'epon" or "araldite") into manufacturing plants where workers had been hitherto unfamiliar with chemical processes brought the workers into contact with substances that carried an unknown risk to the skin The case histories and patch tests showed that the skin reactions follow contact with the liquid stage of the resin and hardener or with mixtures of these before setting is complete This applies both to the apparent direct irritation and sensitization A mean time of setting is about 48 hours, before which time contact with the material should be prevented The set, hardened resin appears to be innocuous as far as skin reactions are concerned The vapor pressures of the casting resin and of the hardener are so low that atmospheric concentrations are negligible in respect to the early and sensitization effects While the direct contact of the liquid materials with the skin seems to be the chief problem, there is a possibility that even the low concentrations of resin or hardener vapors may be sufficient to induce a recurrence in a sensitized subject

Workers should be trained by experienced men how to use these resins and should be told that traces of the casting resin on tables, chairs, shoes, clothes, machines, buttons, door handles, pencils, etc , may be the source of skin inflammations The work bench should be covered by a strong paper on to which the casting resin may drip to prevent permanent contamination The soiled paper could be removed twice daily and destroyed Fresh cleaning rags should be supplied daily and used only for occasional cleansing of apparatus, machines, and containers Contaminated rags should be handled with gloves The use of solvents for removing spots of resin on the skin or nails should be abandoned When apparatus is cleaned with solvents, the worker should wear gloves of polythene Ketonic solvents are preferable The well known objection to gloves in work of this kind can to some extent be overcome by the use of soft leather gloves with knitted backs or, alternatively, thin cotton gloves under polythene Barrier creams have their place in protecting the skin in this work, especially the face It is desirable to install facilities for washing in the working room Finger nails should be kept short and clean After the day's work washing should be followed by inunction of the hands with a mild fatty ointment Preemployment medical examination should eliminate persons with allergies from work in these processes If the initial stage of skin irritation develops, an attempt can be made to prevent sensitization, but, if it does result, there must be no further work with the resin

BOOK REVIEWS

Practical Diagnosis and Treatment of Liver Disease By Carroll Moton Leevy, M D, Director of Clinical Investigation Director of Outpatient Department, and Attending Physician, Jersey City Medical Center, Jersey City, N J Foreword by Franklin M Hanger, M D, Professor of Medicine, College of Physicians and Surgeons, Columbia University, New York Cloth $8 50 Pp 336, with 84 illustrations by Felix Traugott Paul B Hoeber, Inc (medical book department of Harper & Brothers), 49 E 33rd St, New York 16 1957

This is a practical and relatively condensed book on liver disease written for the clinician A composite approach to diagnosis and treatment with correlation of clinical and laboratory findings is stressed The first five chapters deal with the diagnostic significance of the various clinical and laboratory findings Chapter 6 is concerned with general principles of therapy Treatment of fluid retention, electrolyte disturbances, coma, and hematemesis is included There is a brief discussion of the surgical procedures available for the latter The tone of this chapter is practical, and there are convenient tables and diet lists The final chapters deal with liver disease due to nutritional deficiencies and metabolic disturbances, toxipathic liver disease, circulatory disturbance, biliary obstruction and infection, neoplastic disease of the liver, and trauma The presentation is clear, concise, and readable The bibliography is selected but adequate for the purpose of the book Theoretical discussion is minimal The print is unusually clear, as are the diagrams and tables The color plates are excellent This book is recommended for the practitioner who needs a concise clear guide to the management of the more common problems encountered in patients with liver disease

The American Academy of Orthopaedic Surgeons Instructional Course Lectures Volume XIII Editor R Beverly Raney M D Cloth $12 Pp 327, with illustrations J W Edwards Ann Arbor, Mich, 1956

The American Academy of Orthopaedic Surgeons, at its annual meetings during the past 15 years, has offered instructional course lectures that supplement the papers and discussions given in the scientific sessions The subjects for these lectures are carefully chosen and include many of the fundamental concepts and basic techniques used in the practice of orthopedics These are generally presented by authors who themselves have devised the techniques or have made special studies and contributions to the subject under discussion Thus, at each meeting an opportunity is provided for each member or guest of the academy to select a group of lectures on subjects of interest to him or about which he wishes to refresh or supplement his knowledge Through the years these lectures have been so popular that they have been published in book form These annual volumes constitute a valuable reference library for practicing surgeons, residents, and students Volume 13 contains 27 articles with appropriate illustrations Among these are four on the hip, one on the spine, eight on neuromuscular diseases, three on diseases of bone, and three on traumatic lesions In addition, there are articles on more general topics, such as anatomy and physiology of the bone and joints, bone tumors, vascular lesions, disability evaluation, medical writing, and medical education

The Recurrent Laryngeal Nerves in Thyroid Surgery By William H Rustad M D Assistant Clinical Professor of Surgery University of California School of Medicine, San Francisco Cloth $4 50 Pp 47 with illustrations by Ralph Sweet Charles C Thomas Publisher 301-327 E Lawrence Ave, Springfield, Ill, Blackwell Scientific Publications, Ltd 24-25 Broad St, Oxford England, Ryerson Press 299 Queen St W Toronto 2B Canada 1956

This monograph is a study of the extralaryngeal portions of the recurrent laryngeal nerves on the right and left sides of the neck Although 250 nerves were dissected in 125 cadavers, it was thought best to report on the 100 specimens that remained intact on complete exposure Such painstaking dissection in an area where variations are the rule is commendable Equally praiseworthy are the clear and accurate illustrations Much worthwhile material has been presented Of the 200 nerves dissected, 57% were found to be single trunk nerves while the rest were divided Bilateral division occurred in 24% of the specimens This nerve may branch at any point peripheral to its separation from the vagus nerve The point at which this nerve is most vulnerable during a thyroidectomy is on the posterolateral surface of the thyroid gland at the level of the junction between the middle and lower thirds Here the main branches of the inferior artery usually enter the gland An interesting section on historical background and grouping of the patterns and a bibliography are included This book can be highly recommended to surgeons and anatomists

Morals in Medicine By Thomas J O Donnell S J, Regent and Professor of Medical Ethics Georgetown University School of Medicine Georgetown University Hospital Washington D C Cloth $3 75 Pp 281 Newman Press, Westminster Md 1956

The author correctly defines ethics as ‘an investigation into the goodness or evil of human actions in the light of natural reason’ He has sought to extract from ethics, moral theology, and canon law the principles of each as he thinks they should apply to the actions of members of the medical profession If the triad of disciplines on which this book rests is accepted by the reader as proper and germane, then there can be no disagreement with the author on the score of the treatment of the subject as he has outlined it Very probably he is a skilled theologian and a man learned in canon law, but the application of principles of moral theology and canon law to ethical principles, as such principles apply to the practice of medicine, is a proposition that must be accepted or rejected by the individual physician, exactly as he must accept or reject the principles of deism in his own life

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated

The eight chapters which comprise this book contain much that is both provocative and enlightening In the third chapter, on the inviolability of human life, the definition of the fundamental equality of all men in the words "they all have the same final destiny or end in life, and are all equal in their intrinsic dignity as human beings" seems especially commendable Such perplexing subjects as euthanasia, suicide, prolongation of life in the face of a terminal illness, mutilation, contraception, needless surgery, ghost surgery, prefrontal lobotomy, experimentation on human beings, professional secrecy, abortion, problems of marriage, and many others are treated in a resolute manner by the author according to the system mentioned The book will be instructive to the physician who seeks a guide to his own professional conduct based on theology and morals as they affect ethics The work does not inquire extensively into ethical problems encountered among physicians in their relations with one another, as opposed to ethical problems arising between physician and patient, but it was not intended as a commentary on the former category

The Clinical Management of Varicose Veins By David Woolfolk Barrow, M D, Professor of Surgery Marquette University School of Medicine, Milwaukee With foreword by Arthur W Allen, M D Second edition Cloth $6 Pp 169, with 74 illustrations Paul B Hoeber Inc (medical book department of Harper & Brothers), 49 E 33rd St, New York 16 1957

This is the second edition of a highly successful, concise, and clearly written monograph, eminently suitable for the general surgeon and also the general practitioner doing his own surgery Perhaps the most attractive feature of the book is the detached, unbiased attitude of the author toward accomplishing the objectives of treatment While he describes his own experience precisely, he calls attention to controversial points The author's enthusiasm for femoral vein ligation for postphlebetic sequelae is not shared by this reviewer The style is simple and direct, the illustrations are many, and the printing is excellent

Clinical Physiology The Functional Pathology of Disease Edited by Arthur Grollman, M D, Ph D F A C P, Professor and Chairman of Department of Experimental Medicine, University of Texas Southwestern Medical School Dallas Cloth $12 50 Pp 854, with illustrations Blakiston Division, McGraw-Hill Book Company, Inc, 330 W 42nd St New York 36, 95 Farringdon St London, E C 4, England, 253 Spadina Rd, Toronto 4 Canada 1957

This book, the work of 26 contributors, attempts to present basic physiological principles in relationship to clinical medicine In general this has been accomplished exceedingly well, largely because the editor has chosen clinicians whose research has been in the field of human physiology Among these are the recent Nobel prize winners, Cournand and Richards, who have done a superb job with the section on the respiratory system Chapters on carbohydrate, lipid, and protein metabolism were completed by Dr John P Peters just before his untimely death The cardiovascular, digestive, endocrine, renal excretory, hematopoietic, and locomotor systems are all covered in this book There is also a chapter on infection and immunity References are given at the end of each chapter A few diagrams and tables supplement the text in appropriate places This is an excellent book for the internist and the hospital resident who would like to correlate physiological concepts with what is found in the diseased patient

Radiology of the Alimentary Tract in Infancy By Roy Astley, M B, M R C S, D M R, Radiologist, Children's Hospital Birmingham, England Cloth $10 Pp 287, with illustrations Edward Arnold & Co, 41-43 Maddox St, London, W 1, England, Williams & Wilkins Company, Mount Royal and Guilford Aves, Baltimore 2, 1956

By combining roentgenograms, schematic drawings, and terse case summaries with observations and comments based on broad clinical experience, the author has realized his stated aim to produce a volume primarily for radiologist and radiologist trainee and useful to both pediatrician and pediatric surgeon A great deal of highly pertinent material which deals with the radiologic aspects of gastrointestinal situations solely or primarily encountered in infancy is presented This is arranged in seven anatomic subdivisions Commendable brevity has been achieved, with no sacrifice of important content material and no compromise with clarity of discussion The various developmental faults responsible for sometimes fatal and often obscure alimentary difficulties are particularly well presented and documented By the avoidance of repetitive discourses on subjects that are not peculiar to infants, the pediatric keynote has been preserved throughout each subdivision The outstanding excellence of literary content is matched by similar stellar performance by the publishers Reproduced roentgenograms, always critically examined by radiologists, are of fine quality This book merits attentive reading by radiologists and pediatricians and an honored place on the reference shelf

The Gist of Obstetrics By H B Atlee M D F R C S F I C S, Head of Department of Obstetrics and Gynecology Dalhousie University, Halifax, N S, Canada Cloth $6 Pp 327, with 88 illustrations by Garth Vaughan, M D, C M Charles C Thomas, Publisher, 301-327 E Lawrence Ave Springfield, Ill, Blackwell Scientific Publications, 24 25 Broad St, Oxford, England, Ryerson Press, 299 Queen St, W, Toronto 2B, Canada, 1957

This book is based on lectures given by the author to his students It therefore contains data based chiefly on his personal experience It is not intended as a reference book in the manner of the larger standard textbooks on obstetrics The author is partial to natural childbirth and is opposed to the widespread prophylactic use of forceps He does, however, consider forceps on the after-coming head in breech deliveries the method of choice In general, the advice given is in accord with that practiced in the United States and Canada The illustrations are simple line drawings, but they are clear and instructive There are no references, but this is because the book is a personal one. The author has a keen sense of humor which is evident throughout the book This type of teaching is undoubtedly of great help to students, hence this book should be most valuable to medical students if used in conjunction with the standard textbooks of obstetrics

QUERIES AND MINOR NOTES

PROPHYLAXIS OF AMEBIASIS

TO THE EDITOR —*What is the value of the prophylactic treatment of amebiasis with antiamebic drugs? A number of persons return from Mexico with severe amebic dysentery in spite of hygienic precautions This dysentery frequently proves refractory to treatment with all the modern amebicides The statement has been made that prophylactic treatment with antiamebic drugs is not indicated because it may simply "mask' the infection or cause the amebas to become 'drug-fast' What is the rationale of allowing individuals to acquire a full-blown or possibly a fulminating infection if prophylaxis is possible? Have any studies been made as to the value of chemical pro phylaxis in amebiasis? Please outline in detail a suitable regimen for the prophylactic treatment of amebiasis Which drug would be most effective? What would be the daily dosage, and for what period of time should the drug be taken? Would a combination of drugs, taken either simultaneously or in succession, be more effective?*

M D, New York

This inquiry has been referred to four consultants, whose respective replies follow —ED

ANSWER —Craig first suggested the use of amebicidal drugs prophylactically in the prevention of amebiasis (*Am J Trop Med* 20 799, 1940) He proposed Diodoquin (5,7-diiodo-8-quinolinol) for this purpose and believed that, if administered in therapeutic amounts daily, the drug would probably destroy any amebas that might be ingested However, this schedule was not supported by any clinical investigation

Recently Beaver and others (*Am J Trop Med* 5 1015, 1956) have demonstrated the chemoprophylactic properties of Diodoquin when administered to volunteers who were experimentally fed cysts of Endamoeba histolytica on several occasions at weekly intervals They found that the daily administration of 650 mg of Diodoquin, begun one week before the first feeding of cysts and continued for one week after the last feeding, completely protected all of nine volunteers against infection Similar experiments with glycobiarsol (Milibis) demonstrated that this drug, in daily doses of 250 mg, protected 8 subjects against infection, although there was one apparent failure among 14 subjects in additional trials in which the number of cysts was twice that given the initial 8 subjects It is probable that either drug would furnish effective suppression under circumstances that might provide casual or intermittent exposure to small numbers of cysts of E histolytica The drugs could be taken for a period of at least one month in the doses used in the above trials

ANSWER —There have been several demonstrations of so called chemotherapeutic prophylaxis of amebiasis in mental institutions and one in a hyperendemic area in Central America Mass treatment of groups having a high prevalence of infection has reduced prevalence practically to zero, the continuance of the chemotherapy for weeks or months has prevented reinfection from infected contacts There are no known reports of studies of chemoprophylaxis in uninfected individuals going to hyperendemic areas If chemoprophylaxis is desired, it can probably be accomplished by taking iodochlorhydroxyquin (Entero-Vioform), 0 25 Gm twice daily, or Milibis, 0 5 Gm three times daily twice a week, for the duration of exposure but not longer than a month There is no advantage in taking a combination of drugs simultaneously, but they might be taken in succession However, it is believed that it is preferable to avoid salads and unsafe water and to treat gastrointestinal symptoms as soon as they occur Bacillary infections seem much commoner than amebic and can be quickly combatted by therapeutic doses of Entero-Vioform or a sulfonamide There does not seem to be any evidence that E histolytica becomes drug-fast, but it is recognized that some patients require a change of treatment in order to obtain a cure Early cases of amebic dysentery rarely are refractory to chemotherapy with the modern amebicides Persons with refractory cases should be examined carefully by an expert technician to determine whether there is some other etiological agent

ANSWER —In general, for prophylaxis, tourists or travelers take one Entero-Vioform tablet in the morning and one at night This dosage schedule, in the great majority of instances, is adequate to prevent diarrhea and has the added advantage that the traveler need not carry pills around all day long However, some travelers do take 1 tablet with each of the three daily meals No sufficiently critical study has been done that could supply a definite dosage schedule Dr McPhee, from Princeton, had good luck with our athletes at the Pan-American games with 2 Entero-Vioform tablets daily

If diarrhea develops, the dose should be increased in proportion to the severity of the diarrhea Since Entero-Vioform is practically nontoxic, one does not have to worry about side-effects From 4 to 6 tablets daily will usually clear up such nonspecific diarrhea in a matter of a day or two, and then, when the symptoms have disappeared, the prophylactic dose can be resumed The use of Entero-Vioform has been mentioned by Hughes (*J A M A* 150 1456-1459 [Dec 13] 1952) and by Bercovitz (*Bull New York Acad Med* 24 51, 1948)

The answers here published have been prepared by competent authorities They do not however, represent the opinions of any medical or other organization unless specifically so stated in the reply Anonymous communications and queries on postal cards cannot be answered Every letter must contain the writer s name and address but these will be omitted on request

ANSWER —Entero-Vioform is of special value in treatment of amebiasis and is believed by many laymen outside the United States to be of value also against the bacillary dysenteries Therefore, on the basis of these assumptions, suppressive doses of 0 4 Gm given orally twice daily might be effective in endemic areas However, the usual precautions of avoiding contaminated food should be maintained The sulfonamides have been recommended also, but, like the tetracyclines, their daily use by laymen, without medical supervision, may sensitize or cause untoward effects in a fair number of susceptible individuals

ALCOHOLISM AS A MEDICAL ILLNESS

To THE EDITOR —*I have read much on the acceptance of alcoholism as a disease but have always felt that this is a moral or social problem rather than a medical one I also feel that cirrhosis of the liver and psychosis would more likely have nutritional deficiency bases Could you tell me what the grounds are for considering alcoholism as a medical illness?*

M D , New York

ANSWER —A disease is defined as follows In general, any deviation from a state of health, an illness or sickness, more specifically, a definite marked process having a characteristic train of symptoms It may affect the whole body or any of its parts, and its etiology, pathology, and prognosis may be known or unknown

A disease can also be classified according as to whether it is of primary or secondary origin All patients suffering from the disease process known as alcoholism are also known as problem drinkers The term 'problem drinker" has more of a moral and social implication and exemplifies that type of reasoning However, alcoholism does denote a condition in which there is a deviation from a state of health Alcoholism can be classified into (1) primary alcoholism, which includes (*a*) those patients who from the very first drink of an alcoholic beverage are unable to control their desire for it and (*b*) those who through use over a great many years have developed an inability to take a drink or leave it alone and have become like group (*a*), and (2) secondary alcoholism, which includes those who use alcohol for its sedative action as a means of escape from reality and, in particular, from their personal problems, which are usually on a psychosomatic basis This secondary group comprises by far the majority of patients suffering from alcoholism, however, most alcoholic patients prefer to be in the primary group

Regardless of which group an individual belongs to when under the influence of alcohol, he is ill The member of the primary group is not ill between episodes of drinking, but neither is an allergic person, unless exposed to the allergy This does not necessarily imply that primary alcoholism is an allergy, it may be more akin to the excitement that certain drugs may produce (such as barbiturates and morphine) in some patients, since the action of alcohol is similar to sedatives and volatile anesthetics, such as ether

However, the controversy as to whether alcoholism is or is not a disease is related to the voluntary aspects of the condition in a manner similar to narcotic addictions Anyone can become addicted to narcotics or alcohol if he uses enough each day and for a long enough period Both addictions are characterized by withdrawal symptoms, and the withdrawal symptoms can be prevented in both cases by substitute sedative therapy

In chronic narcotic use, it has been shown (*Science* 124 263 [Aug 10] 1956) that continuous use of narcotic drugs inactivates the demethylating enzymes, although no similar mechanism has been shown for alcohol, some such altered physiological state might exist

Simply because there is a moral and social aspect to this disease does not give physicians the right to deny its existence as a disease, any more than they would be able to deny the existence of venereal disease, which is usually quite obvious As to whether alcoholism is a moral or social problem, rather than a medical one, all that can be said is that that is purely a matter of opinion and feeling, and undoubtedly both approaches are of value The complications of alcoholism are undoubtedly nutritional, since the withdrawal syndrome (delirium tremens) can occur even if the diet and vitamin intake is more than adequate

MUSCULAR DYSTROPHY AND HEREDITY

To THE EDITOR —*A 35-year-old man, height 5 ft 10 in (178 cm), weight 115 lb (52 1 kg), has muscular dystrophy that began when he was 16 years old The process started in his shoulder muscles and now involves almost the entire musculature of his body, except for the forearm muscles He is still able to walk and works sitting at a bench He suffers no pain in particular and seems to have a good attitude toward his disease He has a daughter 10 years of age who at present has no signs of muscular dystrophy, but he is wondering whether she will be a victim of it, inasmuch as his mother, who is now bed-ridden, his uncle on his mother's side, and a brother, who is now confined to a wheel chair, all have muscular dystrophy What can be done for him by a general practitioner?*

J W Wentz, M D , Pataskala, Ohio

ANSWER —This patient undoubtedly has muscular dystrophy On the basis of the fact, however, that onset was in adolescence and that many members of the family of both sexes are affected, as well as on the basis of the distribution of the atrophy, this would seem to be the type that first involves the limb girdles The mode of inheritance of this type is not known quite as well as that of the pseudohypertrophic variety, which is a sex-linked recessive, and of the facioscapulohumeral type, which is usually dominant Consequently, it is rather difficult to state whether the daughter will develop the difficulty or not, but, because of the high incidence in the family and the relatively late onset, there is certainly a possibility that she may There are no suggestions regarding therapy other than general supportive measures and possibly physiotherapy to prevent the development of contractures Mechanical aids should be used if indicated

RECURRENT THROMBOPHLEBITIS

To the Editor —*A 55-year-old man sustained a displaced fracture of both bones of the left forearm On the day of injury, an open reduction and internal fixation with bone grafts obtained from the anterior iliac spine of the patient was performed The arm was placed in a cast, and the patient did well for approximately 12 days postoperatively He had been discharged from the hospital and was at home walking around when he was seized with a severe pain in the right side of his chest, accompanied by a slight elevation in temperature He was admitted to the hospital, and x-rays were taken that revealed a wedged-shape infarct in the right lower lobe, which in the opinion of the consultants represented a probable pulmonary embolus Dicumarol therapy was started, with complete relief of pain in the chest At no time has the patient ever had any peripheral signs of thrombophlebitis, either in his legs or in his arms He never complained of any calf pain, nor was there ever any calf tenderness Dicumarol therapy was continued for 14 days, and two days after it was discontinued the prothrombin time had become elevated The patient had another episode of pain in the left side of his chest, and again x-rays revealed a pulmonary infarct in the base of the left lower lobe He was again treated with dicumarol, this time for a period of seven weeks and again at no time was there ever any sign of peripheral thrombophlebitis It was assumed that the patient had thrombophlebitis of the pelvic veins The patient also never had any unusual pain or swelling in his left upper extremity, and, as a matter of fact, 12 weeks after the original operation, he has had union of the fractures and has complete motion in his forearm as regards supination and pronation The question has arisen whether this patient will have any permanent disability as a result of the thrombophlebitis of the pelvic veins How much disability is this man expected to have because of the thrombophlebitis, and what is the opinion as regards recurrence of the thrombophlebitis if he has another serious illness or major surgery?*

Robert T Strang, M D , Kingsport, Tenn

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —On the basis of what has been presented the source of the pulmonary emboli is a matter of conjecture only The emboli most likely arose from the veins in the affected arm Since there is no good evidence that the patient ever had pelvic thrombophlebitis, it seems doubtful that he will ever have any permanent disability Yet, if the patient ever undergoes a major operation or has a serious illness, the chances are good that he will be more susceptible to thromboembolic complications than one who has not had the episodes reported, and he should, therefore, be given anticoagulants, provided there is no contraindication to their use

Answer —The absence of signs of peripheral thrombophlebitis does not rule out the possibility that clots were present in the iliac veins This could have been the source of the pulmonary emboli There would have been more symptoms with a pelvic phlebitis than with a quiet type of iliac vein clot If the pulmonary emboli are the result of bland clots in an iliac vein, then there will probably be no disability, since there are no symptoms to begin with in the extremities of this patient Also, the entire clot may have traveled to the lungs Although one cannot predict whether thrombophlebitis will or will not occur in an individual who has had one episode, should he have another serious illness or major surgery he would have to be watched closely and, if there is a slight rise in temperature, he should be placed on anticoagulant therapy In addition during any such serious illness his legs should be elevated and exercised as often as possible to keep the blood moving The legs should be examined daily during such a period

GLYCOSURIA DURING FEBRILE ILLNESS

To the Editor —*A 6-year-old girl, weight 50 lb (22 7 kg), had been having an intermittent fever, etiology unknown, for two weeks One day after the fever disappeared a urine specimen showed 2% sugar and was strongly positive for acetone Three days later a glucose-tolerance test was reported as follows fasting 134, one-half hour after administration of 50 Gm of glucose, 198, one hour later, 157, two hours, 128, and three hours, 138 mg per 100 cc All urine specimens were normal All blood sugar tests were microscopic Two years ago, during an upper respiratory infection, two urine specimens also showed a trace of sugar The child is active and has developed normally in every respect Should a diagnosis of diabetes be entertained here?*

Louis E Itzkowitz, M D Brooklyn, N Y

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —Transitory glycosuria occurs not infrequently among children during infections, and acetonuria likewise occurs frequently among normal (nondiabetic) children after fasting or inadequate food intake In the absence of other symptoms it is unlikely that the child described has diabetes mellitus, but the possibility should indeed be borne in mind In such a case it would be wise to have occasional tests of the urine for sugar after generous carbohydrate meals especially during colds or other acute illness

Answer —The fact that the child had two urine specimens that showed a trace of sugar (or reducing substance) during an upper respiratory infection probably means nothing important, as many children have some reducing substance in their urine during acute febrile illness The 2% sugar and strongly positive acetone found in the urine the day after the two weeks of fever is peculiar The child may well have eaten poorly, and the acetone could easily be explained by loss of glycogen reserves caused by fever and poor appetite A 2% sugar level, however, is difficult to explain, as this finding probably means that the child had as strong a sugar test as is possible to obtain by qualitative methods, and she should not have had any sugar in her urine at this time It is presumed that the glucose-tolerance test was an oral one and that the blood sugar tests were run by a method which measures total reducing substance rather than true blood sugar The amount of glucose given is about 10 Gm greater than is usually employed on children of this weight The shape of the curve is, however, not abnormal, but the values are all high If they are correct it is surprising that no sugar was found in the urine when the value reached 198 mg per 100 cc If the child has diabetes, it would be very strange that, three days after having much sugar and acetone in the urine, both should have disappeared and the shape of the tolerance curve should be normal rather than the prolonged high curve found in diabetes While it is not thought that the child has diabetes, it is wondered if the blood sugar values are correct, and not all read higher than they really were If there is diabetes in the child's family, it might be well to repeat the tolerance curve at a later date, perhaps using a different laboratory, otherwise, these peculiar laboratory findings can be disregarded

HARMFUL EFFECTS OF DAILY ENEMA

To the Editor —*Is there any possibility of harm from using the Fleet Enema daily? A patient began using it about two years ago and has found it indispensable*

F Paul Ansbro, M D , Brooklyn, N Y

Answer —There are no known clinical or experimental observations that would enable one to answer this question definitely This consultant believes that no harm will result if the enema is used on a short-term basis, e g , for several days, however, even under this condition there should be endoscopic control Potential harm could result from long-term use because (1) it is unphysiological, (2) there could possibly be trauma to the anal canal incident to the daily insertion of the hard plastic tip (this consultant has observed such trauma a number of times after single insertions), (3) the passage of the excessive amounts of mucus produced by this concentrated salt solution might have an adverse psychological effect, and (4) frequent manipulation by the patient of the anal region, which is an erogenous zone, is inadvisable Use of this concentrated salt enema should also be avoided by patients who require stringent salt restriction

EFFECT OF RADIOACTIVE IODINE ON PARATHYROIDS

To the Editor —*Can 'atomic cocktail therapy for hyperthyroidism affect the parathyroid glands in such a way as to cause hypoparathyroidism? This condition seems to have occurred in a patient who also has myxedema*

J K Fancher, M D , Atlanta, Ga

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —At a recent conference sponsored by the Atomic Energy Commission, the 10-year experience with radioactive iodine (I^{131}) therapy for hyperthyroidism and thyroid cancer was reviewed A com bined series of approximately 13,000 patients treate in a number of clinics was available for analysis N instance of hypoparathyroidism was reported afte treatment Beta rays, released by disintegration of I^{13} are absorbed within 2 to 3 mm of tissue Since thes provide most of the radiation effect from I^{131}, it i theoretically unlikely that normal parathyroids woul be exposed to serious injury Injury would be hypo thetically possible, however, if the parathyroids wer anomalously placed and buried in hyperfunctionin thyroid parenchyma Injury to normal parathyroi has not been reported after external radiation therap even with dosages directed against cancer in neig boring structures However, Jacox has reported a increased sensitivity of hyperfunctioning parathyroi to the effect of radiation It is thus conceivable th a patient with subclinical hyperparathyroidism, give radiation therapy for hyperthyroidism, might suffe parathyroid injury The number of patients treate with I^{131} is now sizable, so that, according to th laws of chance, spontaneous idiopathic hypoparathy roidism might be expected to occur in a few patien receiving I^{131} therapy

Answer —Large numbers of patients have now re ceived I^{131} in therapeutic doses, many of them ver large doses designed to destroy the thyroid gland or t treat cancer of the thyroid, but up to the present ther is only one known report in the literature of temporar parathyroid insufficiency following I^{131} therap (Tighe *J Clin Endocrinol* 12 1220, 1952) A wel documented case should be considered for reporting i the literature

CAFFEINE AND ULCERS

To the Editor —*The 1955 edition of Goodman an Gilman's 'Pharmacological Basis of Therapeutics (ed 2, New York, the Macmillan Company) indicate that caffeine, even more than alcohol, in its stimul tion of gastric acid production, distinguishes be tween ulcer victims and normal persons The stimu lation of the stomach by alcohol is a direct effe and does not depend on the mediation of the nervo system What is supposed to be the mechanism the stimulation by caffeine? Since, according Goodman and Gilman, amphetamine does not stim ulate production of gastric acid, presumably nervo connections, if involved, do not depend on stimul tion of the cerebral cortex Is an intact vagus nerv necessary for the stimulation by caffeine? Will par sympathetic inhibitors, such as atropine or Banthin destroy the effect of caffeine? Patients taking Ban thine, for instance, often ask if they may be pe mitted alcohol or coffee*

Alfred B Mason, M D , Concord, Calif

Answer —The exact mechanism of stimulation b caffeine of gastric acid secretion is unknown It doe not result from a central nervous stimulant effect caffeine, and the vagus nerve need not be intac whether intramural ganglions are necessary has no been determined Available evidence suggests th caffeine directly stimulates the parietal cells It al enhances the gastric secretory response to alcohol, histamine, acetylcholine and its congeners, meat extractives, and electrical stimulation of the vagus The enhancement of the vagal effect is most likely explained by the fact that acetylcholine is released peripherally when the vagus is stimulated Parasympathetic blocking agents, such as atropine and synthetic substitutes for atropine, moderately reduce but do not abolish the stimulation by caffeine of gastric acid secretion This is also true for the stimulation by alcohol and histamine

LIPOTROPIC DRUGS

To the Editor —*A number of medical products for use in geriatric practice contain inositol, choline, and methionine Has the therapeutic value of these substances been established?* *M D , Florida*

Answer —Inositol, choline, and methionine were introduced and used for the purpose of reducing heightened blood cholesterol levels They have some effect but little therapeutic value, and their use has markedly decreased A panel of nutritionists and clinical and laboratory specialists, at a recent meeting of the American Geriatrics Society, were unanimous in the opinion that these drugs give no service in prevention or therapy

Answer —Although a relatively large number of published experimental and clinical studies have hinted at the possibility of modifying arteriosclerotic changes in humans by the administration of lipotropic agents and other drugs, there seems to be no conclusive evidence establishing the therapeutic value of these preparations for this purpose The report of Moses (*J A M A* 156 492-493 [Oct 2] 1954) points out that there is no acceptable evidence in either man or animals that atherosclerotic lesions can be retarded or reversed by the administration of either one or several lipotropic agents in combination, and there is considerable evidence that the administration of large amounts of these dietary supplements to patients with moderate degrees of hepatic damage may be detrimental A reply to a query in The Journal for Feb 12, 1955, page 625, expresses the opinion that, despite some reports, the evidence of a definitely favorable effect of lipotropic agents in retarding the progression of atherosclerosis is inconclusive

POTENCY OF ASCORBIC ACID AFTER STORAGE

To the Editor —*If orange or grapefruit juice is strained from the natural fruit and placed in a pitcher or glass, will it keep for a period of from one to three days in the refrigerator without any decrease in the content or potency of ascorbic acid (vitamin C)?*

Harris P Dawson, M D , Montgomery, Ala

Answer —The amount of ascorbic acid lost from fresh orange juice that is stored for 24 hours in a covered glass or china container in a refrigerator is negligible Moore and associates, cited by Sweetman and MacKellar in Food Selection and Preparation' (ed 4, New York, John Wiley & Sons, Inc , 1954), reported in 1945 that, even when orange juice is kept uncovered in a refrigerator for as long as a week or at room temperature for three days, there is little change in the ascorbic acid content, however, there is better flavor when the juice is covered and stored in a refrigerator for no more than three days

WESTERGREN SEDIMENTATION RATE TECHNIQUE

To the Editor —*I am writing in reference to the query and minor note in* The Journal *of Dec 29, 1956, page 1674, regarding the Westergren sedimentation rate technique We use the Westergren method as regular office procedure on our patients and have been using a different normal range The consultant states that the normal for men is 1 to 3 mm and for women, 4 to 7 mm*

We are using a Westergren pipette, 300 mm long, 2 5 mm in diameter, graduated in millimeters up to 200 mm We use a 3 8% solution of sodium citrate This apparatus is made by Clay-Adams and the normal with this method is 0 to 15 mm for men and 0 to 20 mm for women after one hour I have checked other laboratory sources and find this to be the most frequently used normal standard for the Westergren method

*I noticed the reference to Ham and Curtis (*Medicine *17 447, 1938) as the source of reference I would appreciate the explanation of the great difference in normal standards recommended*

Arthur W Greenfield, M D
50 Anderson St
Hackensack, N J

The above comment was referred to the consultant who answered the original query, and his reply follows —Ed

To the Editor —*It is agreed that a Westergren pipette is 300 mm long, 2 5 mm in internal diameter, and that when the blood is drawn up to a 200 mm mark it contains about 1 ml of blood The anticoagulant is an aqueous solution of 3 8 gm of sodium citrate per 100 ml This is used in a preparation of 0 2 ml of anticoagulant for every 0 8 ml of whole blood, making a final concentration of 760 mg of sodium citrate per 100 ml and a dilution of 20% of the blood with an aqueous solution*

Westergren, himself, gives the normal range of it to be 1 to 3 mm sedimentation for men and 4 to 7 mm sedimentation in one hour for women Other values that are higher are probably not normal and may be contributed to by anemia per se

VITAMIN K ADMINISTRATION

To the Editor —*The reply to the query on vitamin K administration, which appeared in* The Journal, *Jan 26, 1957, page 327, is somewhat misleading It is stated that 'vitamin K_1 appears to have some superiority over synthetic vitamin K preparations in the treatment of idiopathic hypoprothrombinemia' If the idiopathic type is considered the same as the congenital and hereditary types, that statement is* *erroneous, since neither the natural nor the synthetic vitamin K corrects the deficiency of this type of prothrombin activity In vitamin K deficiency such as occurs in the newborn infant or in the patient with obstructive jaundice both types of vitamin K are effective, but in the latter condition the synthetic water-soluble vitamin K has the advantage that it can be absorbed from the intestines in the absence of bile Excess amounts of vitamin K can depress the prothrombin time, particulaly in the presence of liver disease (Richards and Shapiro* J Pharmacol & Exper Therap 84 93, *1945)*

Armand J Quick, M D
Department of Biochemistry
Marquette University School Medicine
Milwaukee 3

The above comment was referred to the consultant who answered the original query, and his reply follows —Ed

To the Editor —*In regard to the literature reference cited, while the citation is essentially correct from the contents of the paper, it may be worth while to quote the following from the authors' conclusions to this paper 'In man doses approximately ten times as great as those generally recommended for therapeutic use, given daily for a period of one week, induce no significant changes in the blood In normal subjects large doses of Hykinone can produce temporary hyperprothrombinemia, in cases of liver disease similar amounts of menadione bisulfite extend the prothrombin time"*

RECURRENT FACIAL SEBACEOUS CYSTS

To the Editor —*In the March 23, 1957, issue of* The Journal, *page 1095, under Queries and Minor Notes, there are discussed various surgical approaches for the treatment of recurrent facial sebaceous cysts May I offer a simple, but apparently not too widely known, procedure which I use in my dermatological practice for the removal of either sebaceous or epidermal inclusion cysts? The cosmetic result is much better than with scalpel excision and sutures, and the end-result is more complete and dependable than with incision*

The skin over the center of the cyst is anesthetized with Novocain injection With a 4-mm -diameter biopsy punch, a circular piece of skin, including the external portion of the sac wall, is removed Through the remaining hole the sac contents are expressed, and the sac is delivered in toto *with a hemostat Pressure is applied for a minute or two to minimize bleeding, after which the plug of skin, with the sac portion cut away (to prevent future recurrence) is replaced into the hole A dressing is applied and left in place for several days until the graft of replaced skin "takes" In this manner the sac is removed, no skin is lost, and no sutures are required*

A modification for the removal of scalp cysts consists in not replacing the skin plug but placing just one suture to prevent bleeding, since pressure dressings are difficult to apply on the scalp This method also eliminates the necessity of shaving the scalp, except for clipping a few hairs in the tiny operative field I have removed cysts on the scalp the size of an egg by this simple and short procedure

William M George, M D
Walnut Creek, Calif

The above comment was referred to the consultant who answered the original query, and his reply follows —Ed

To the Editor —*There are actually hundreds of methods of removing sebaceous cysts The answer to the original inquiry made no attempt to describe all of them The method presented in the above comment is another good conservative measure for use on the face However, a tiny incision, such as mentioned in the original answer, leaves less scar than a sutured or grafted punch*

DRUGS INTERFERING WITH PROTEIN-BOUND IODINE DETERMINATION

To the Editor —*In a query and minor note published in the Dec 22, 1956, issue of* The Journal, *page 1582, a physician requested a list of drugs capable of causing a distorted blood protein-bound iodine level I noticed that desiccated thyroid, thyroglobulin, thyroxin, and sodium liothyronine (*l*-triiodothyronine, Cytomel) were omitted from this list Of course, it is known that desiccated thyroid, thyroglobulin, and* l*-thyroxin will increase the blood protein-bound iodine levels In contrast, sodium liothyronine will not increase these levels (I have seen no increase in protein-bound iodine values in patients receiving as much as 150 mcg per day) On the other hand, administration of sodium liothyronine may cause a decrease in blood protein bound iodine values, while the patient remains clinically euthyroid Because of the rapid cut-off of effects after withdrawal of sodium liothyronine, protein-bound iodine values generally return to pretreatment levels within a few weeks*

Martin C Sampson, M D
418 S 47th St
Philadelphia

The above comment was referred to the consultant who answered the original query, and his reply follows —Ed

To the Editor —*The original reply to the query and minor note in question was restricted to a consideration of iodine-containing drugs creating spuriously high protein-bound iodine levels The above comment draws attention to another way in which the levels may be effected The failure of sodium liothyronine to elevate protein-bound iodine levels is considered to be due to its rapid escape into the tissues, while the fall in the protein-bound iodine level that is often noted with its use is due to depression of endogenous thyroxin formation*

Loan to Finance Health Projects in Latin America • •
Communists' Payments Cut Proportion of U S WHO Costs • •
President s Aid Asked to Help Enact Jenkins-Keogh Bill • •
HEW Officials Press for Aid-to-Medical-Schools Program • •

LOAN FOUR MILLION DOLLARS TO LATIN AMERICA FOR HEALTH PROJECTS

Two Latin American countries, Costa Rica and Panama, are moving ahead with projects in the health field underwritten by 2-million-dollar loans from the United States, granted by the International Cooperation Administration and handled by the Export-Import Bank Both loans run for 20 years, with interest at 3% if repaid in U S dollars or 4% if repaid in local currencies

Costa Rica will use its loan to help in constructing and equipping a children s hospital at San Jose, the first step in an integrated hospital program for the country A series of small city hospitals will operate in other localities, and the San Juan general hospital in San Jose will be gradually rebuilt

In working out the hospital program, Costa Rica and the United States have cooperated closely over a number of years, according to the ICA Plans and working drawings were handled by a Washington, D C, architectural firm, which also trained six Costa Rican engineers to carry on the project

The ICA reports that the children's hospital plan has aroused great enthusiasm in Costa Rica, and that $187,000 has been raised by popular subscription to help in financing

Panama's 2-million-dollar U S loan, matched by the same amount provided by Panama itself, will be used for construction of a sewerage system and improvements in the water system in the Matasnillo Basin, a suburban area of Panama City that also contains El Panama Hotel, a showplace

U S CONTRIBUTION TO WHO DROPS TO ONE THIRD

For the first time in the nine-year history of the World Health Organization, the U S contribution has dropped to one third of the total WHO budget, although the U S, like other members, is contributing more money this year The information was received in Washington from the Geneva meeting of the World Health Assembly, the governing body of WHO

The decrease in the U S percentage in this year s budget is the result of the return to active WHO membership of Russia and three satellite countries—Albania, Bulgaria, and Poland The total budget will be $10,700,000, of which the U S will pay about $3,600,000 The returning Communist countries will pay a total of $1,500,000

During the period the four countries were inactive, two budgets were prepared each year, the larger one including assessments against the four, because there is no mechanism in the WHO constitution providing for a withdrawal' The American contribution of a "third was calculated on this larger budget The other budget was the actual working budget, smaller than the official budget because the Communist contributions were missing The result was that the U S paid well over a third of the actual expenses

Last year, Congress, at the request of the administration, removed a limitation of 3 million dollars on the U S contribution

Six new states, including the United States, have been selected to name delegates to the WHO executive board, to serve for three years The other nations are Liberia, Australia, Western Germany, Egypt, and Afghanistan Cuba, Russia, and Thailand received votes but were not in the top six

Nations continuing on the board are Argentina, Canada, Ecuador, Finland, India, Italy, Mexico, Pakistan, the Philippines, Portugal, Syria, and the United Kingdom Outgoing members are Burma, Chile, France, Japan, Saudi Arabia, and the Union of South Africa

The board, which meets twice yearly, is composed of international health authorities who are designated by but not representatives of their governments Its functions are to put into effect the decisions and policies of the assembly and to be the assembly s executive organ

Still facing the assembly for a decision is a proposal by the United States to require a two thirds majority of members present and voting for action on budget matters Now these decisions are taken by a simple majority

APPEAL MADE TO PRESIDENT ON JENKINS-KEOGH

An appeal has been made directly to President Eisenhower, asking him to have the Treasury Department reexamine its position and support enactment of the Jenkins-Keogh legislation now before Congress The legislation would authorize the self-employed to put a part of their income into annuity funds, deferring income tax payment on the money until it is received after retirement Corporations now may do this for their employees

The White House was approached by the American Thrift Assembly for Ten Million Self-Employed in a letter signed by Lucius S Smith III, ATA secretary Mr Smith recalled that the President had supported this type legislation in 1952, and added

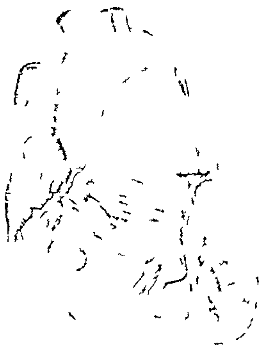
'If [this legislation] now contains any vice, it has eluded several of the foremost tax experts in the nation It is a fact that up to this time no member of the Ways and Means Committee or of the Treasury, or any government spokesman has voiced a single valid objection to the 1957 bill Certainly, 'loss of revenue cannot in our judgment successfully now be argued against this proposal

---

From the Washington Office of the American Medical Association

'LANOXIN'
brand
DIGOXIN

formerly known as Digoxin 'B W & Co'®



for prompt digitalization and dependable maintenance

Dear Doctor:

The new name for Digoxin 'B. W. & Co.' is 'LANOXIN'. This change will now make it easier for everyone to distinguish digoxin from digitoxin.

Now, simply write...

'Lanoxin' Tablets
0.25 mg or 0.5 mg

to provide the safety and predictability afforded by the uniform potency, uniform absorption, brief latent period and optimum rate of elimination of this crystalline glycoside.

A pure, stable, crystalline glycoside isolated from Digitalis lanata...

BURROUGHS WELLCOME & CO (U S A) INC., Tuckahoe, New York

Washington News—Continued

The letter lists the effects the plan would have, including an expansion of the machine of production, "significant" countering of the forces of inflation, "a timely alleviation' of financial stress now endured by the self-employed, and ultimate tax gains because of increases in capital

In conclusion, the message says

"Mr President, we respectfully ask you to examine with your staff the supporting data enclosed herewith [an analysis of the bill] We entreat the support of your administration for a sound and fair proposal, conscientiously drawn to terminate an inequity you long have recognized while at the same time conforming with the Treasury's praiseworthy efforts to counter inflation and encourage real savings

HEW OFFICIAL PRESSES FOR AID-TO-MEDICAL-SCHOOLS BILL

The need for well-trained physicians and other health specialists is one of today's most pressing problems, according to Elliott L Richardson, Assistant Secretary of Health, Education, and Welfare He notes three factors that complicate the situation (1) the growing complexity of medicine and the demands for specialized personnel, (2) the rise of population that by 1960 will total 178 million, and (3) the increasing demand of the American people for first-class hospitals and medical care

Mr Richardson told the Massachusetts Medical Society and the Massachusetts Medical Benevolent Society that one reason the supply-line of doctors is moving slowly is the limited capacity of medical schools to train doctors He suggested the administration's aid to medical-schools bill as a solution to the colleges' need for money to provide necessary laboratories and equipment

A second problem facing the doctors and the American people is the increasing cost of medical care, Mr Richardson declared From 1947-1949 to this year the cost-of-living index has risen 100% while the medical cost index has risen 137% The principal reason for the rise was a 75% increase in the cost of hospitalization Mr Richardson praised the voluntary health insurance companies for helping America solve this problem

Mr Richardson finds a partial solution to the costs of medical care in providing more flexible facilities for those who are not acutely ill More nursing homes and convalescent homes are needed, as well as outpatient clinics and diagnostic centers He points out that the extension of insurance against the costs of out-of hospital care and treatment would ease the cost problem

Mr Richardson concluded on this note

'The medical profession, if it is to live up to its high standards of service to the public, must recognize that the attitude of the American people toward their government has changed considerably in the last quarter of a century There is a greater tendency than in earlier generations to seek advancement of the general welfare through the federal government' But, he continued, 'if the medical profession continues to demonstrate its ability to meet these growing needs of the people, then we may expect our voluntary system not only to survive but to flourish"

Dr Aims G McGuinness, special assistant to Secretary Folsom, speaking before the St Louis Medical Society, also urged passage of the administration's aid-to-medical-schools bill and the health-insurance pooling bill He quoted from Secretary Folsom To fail to help meet the needs of medical schools in this emergency situation would be the worst kind of false economy In referring to the pooling proposal, Dr McGuinness termed it 'an important stimulus for further expansion of similar voluntary programs"

TEN MORE MEDICAL SCHOOLS JOIN MEND

With the addition in June of 10 more medical schools, the Defense Department's Medical Education for National Defense (MEND) program will be operating in 45 institutions, or more than half of the country's medical schools The Defense Department is now sifting applications from about 20 schools that want to participate

Under the program, now in its fifth year, the Defense Department makes available to faculty members the concepts of military and disaster medicine which are constantly being developed by the medical branches of the armed forces Courses, in turn, are developed for the students

The Defense Department, the Public Health Service, and the Federal Civil Defense Administration have joined in the program, which offers medical seminars, teaching materials, and lectures It includes such subjects as the basic principles of field medicine, the physiology of flight, submarine medicine, original research in bacteriology, immunology, and infectious diseases, environmental medicine with reference to survival in all climates, preventive medicine in its broadest scope, problems of atomic, biological, and chemical warfare, and treatment of mass casualties under wartime and disaster conditions

According to Assistant Secretary Frank Berry, the original cost to the Defense Department of the program per school was $15,000, and it is now down to between $9,000 and $11,000

MISCELLANY

Dr John R Heller, director of the National Cancer Institute, has hopes for early detection and successful treatment of five types of cancer through the cytological test, at present applied to uterine cancer The cytological test program, recently proved successful in a pilot project in Memphis, will be extended to include lung, gastrointestinal, urinary, and prostatic cancer The National Cancer Institute has allocated $2,197,000 for the research programs

In the week ending May 17, 2,000,000 cc of poliomyelitis vaccine was released, according to the Public Health Service, with the inventory totaling 8 300,000 cc Since Jan 1 a total of 35,100,000 cc has been produced and released

Four doctors from the National Heart Institute reported to the American College of Cardiology a new technique for locating openings in the heart's middle partition—injecting an indicator dye into the left chamber In the test, as the dye flushes through the tiny arteries of the earlobe, its concentration and transit time are accurately measured and the precise opening can be located

The Senate Committee on Labor and Public Welfare held a special meeting recently to review the artificial-limb research program of the Veterans Administration, the Department of Health, Education, and Welfare, and the Department of Defense The latest devices and techniques were demonstrated while orthopedic surgeons and research workers discussed the program

(cont d)

'LANOXIN' continues to offer the same advantages — only the name has been changed.

The full effects of each dose develop quickly to permit rapid appraisal of the need for additional drug. Moreover, the limits of the patient's therapeutic range, which may be reduced in the seriously ill, may be approached with relative safety because toxicity, if it develops, soon abates. For true balance and uniformity of therapeutic effect, prescribe 'LANOXIN' brand Digoxin.

Sincerely,

'BW&Co'

MAGAZINE—TELEVISION REPORT

The following list of current medical articles in mass circulation magazines and forthcoming network television programs on medical subjects is published each week only for the information of readers of The Journal *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles and programs reported*

MAGAZINES

Coronet, June, 1957

Why I Became a Doctor,' by Albert Schweitzer

An excerpt from Dr Schweitzer's book Out of My Life and Thought, in which the famous physician and humanitarian states 'I wanted to be a doctor that I might be able to work without having to talk

The Right Way to Raise a Bright Child, by Abraham H Lass

The author, a principal of Abraham Lincoln High School, Brooklyn, N Y, recommends early recognition of bright children and special handling of them He writes At best, we don't have too many bright children We can't afford to waste even one'

The Giraffe Nature's Magnificent Mistake,' by Peter Farb

According to the article, the secret to the giraffe's circulation and blood pressure may afford new insight to medical scientists who are seeking to find cures for heart ailments

My Patients Are My God,' by Marcus Bach

According to the article, Dr Shree Murugappa Chennaveerappa Modi has performed more than 40,000 eye operations on his patients in India, 99% of which have been successful Dr Modi is credited with performing 270 operations in a single day

Life, May 20, 1957

Doctor Answers Distant Call

The article gives a brief account, with pictures, of Dr Mikio Kato, 33 years old, of Kobe, Japan, who left his native country to set up practice in isolated Tangier Island, Va According to the article, special aid was needed to bypass immigration difficulties before he could enter the United States

The Saturday Evening Post, June 1 1957

My First Ten Years with a Hearing Aid, by J C Furnas

The author gives a first-hand account of his experience with the new electronic hearing aids and tells how they have helped the hard of hearing

Good Housekeeping, June, 1957

Crisis! Accidental Poisoning?

This article gives an account of the many Poison Control Centers now in operation in various cities in the United States combined with a listing of the centers by states

Family Circle, June, 1957

I Died—and Lived Again, by Catherine Jones

This article tells of how a 43-year-old woman dies while being delivered of a child by cesarean section, and remains dead for eight minutes until cardiac massage, oxygen, and other emergency procedures revive her The mother made a complete recovery, although for a time it was thought she had suffered permanent brain damage

The Better Way in Brief—Radio Controlled Ambulances

A regular *Good Housekeeping* feature describes Mexico City's radio-controlled ambulance service Patients en route to the hospital can be cared for and even prepared for surgery while the hospital prepares for the patient's arrival by communication between the hospital and the doctor in the ambulance

'*Hepatitis—Another* Communicable Disease,' by L Emmett Holt Jr M D

As a part of the magazine's regular feature The Children's Center, the article tells parents how to recognize the symptoms of infectious hepatitis and what they should know about the disease

The American Weekly, June 2, 1957

They've Taken the Risk out of Childbirth by William Engle

In a summary of advances in childbirth technique and prenatal care during recent years, the article states If you are one of those having a baby this year, the chances are about 1,999 out of 2 000 that you will come through safely

specific relief in male climacteric

ORETON

METHYL TABLETS

The *male climacteric* comprises a diverse group of symptoms—including nervousness, irritability, fatigue and depression—which accompany a decline in testicular function In most cases libido and potency are diminished and physical vigor is often impaired

Diagnosis may be confirmed by a simple therapeutic test with testosterone The patient is given 75 to 100 mg of Oreton Methyl Tablets daily for a week or ten days The gradual disappearance of the symptoms and their gradual reappearance after cessation of therapy make the diagnosis of male climacteric reasonably certain Therapy may then be continued with 20 to 50 mg daily

Oreton Methyl Tablets (Methyltestosterone U S P)
Oreton Propionate Solution in Oil (Testosterone Propionate U S P)
Oreton Aqueous Suspension (Testosteorne U S P)
Oreton® Pellets (Testosterone U S P)

For detailed dosage directions consult the Schering Handy Index to Sex Hormone Therapy

SURGICAL MANAGEMENT OF THE SEVERELY BURNED CHILD

Robert S Smith, M D, Boise, Idaho

When a child suffers an extensive third-degree burn, the initial shock of the injury is frequently so great as to threaten an immediate fatality Aggressive and intelligent supportive treatment will give the youthful patient a good chance to survive this first critical period, however In most of these cases, much greater effort on the part of the attending surgeon will be required subsequently before the skin closure which is essential to recovery is obtained Final restoration of body function and features may be achieved only by multiple secondary operative procedures and after a long period of careful surgical supervision

Permanent complete wound coverage by early resection of devitalized tissue and a single application of free sheet-like grafts of skin would provide the ideal solution for most of the problems of the severely burned child In extensive deep burns, with involvement approaching 50% of the body surface, rapid wound closure is usually not possible In these severe cases, the large size of the wounds frequently presents such technical difficulties that operative management in stages is advisable

Biological Dressings

Brown and his associates [1] have presented a good case for the use of skin homografts for early coverage of severe burn wounds Homografts, in effect, have provided biological dressings and have appeared to give lifesaving support to many patients

Grafts derived from cadaver sources may be kept available for emergency use in a skin bank and, when properly applied, will "take" on a burn wound, whether or not donor and recipient blood groups are compatible Apparently as the result of an antigen-antibody reaction, however almost all these homografts will begin to disintegrate after 2 weeks, and their total disappearance may be expected after 8 to 10 weeks In two unusual situations homografts appear to persist indefinitely when a skin graft is transferred from one identical twin to another,[2] and when a skin graft is applied to a recipient with agammaglobulinemia [3]

• Two case histories illustrate the surgical principles involved in the care of the severely burned child A 5 year old girl with extensive third degree burns was carried through the initial period of shock by supportive treatment which included the administration of dextrose, electrolytes, serum albumin, and whole blood by venoclysis Dressings were changed at four to-six day intervals under general anesthesia in the operating room Wound infection was avoided, and sufficient skin for stamp grafts was obtained from donor areas which, since healing, are covered by ordinary clothing A 12-year old girl, seven months after a similar burn, showed severe depletion and anemia, extensive infection, and pressure sores on both hips Multiple transfusions were necessary to improve the general condition of the patient antibiotics stopped the fever Dressings were changed under general anesthesia, and subsequent graftings of skin were successful An aggressive two way plan of action is indicated in severe burns general, systemic measures to combat infection and improve the patient's nutritional state, and specific, surgical measures to bring about the covering of the open wound with skin at the earliest possible moment The skin coverage obtained by stamp like grafts is permanent and in the experience of the author has proved to be of generally good functional quality

After the application of homografts, patients are given vigorous general supportive treatment in preparation for the inevitable replacement of the homografts by autografts Large sheets of the patient's own skin are preferable for replacement procedures, but Brown and Fryer [4] have suggested that, when donor sites are limited, autografts may be placed in strips between dissolving homografts in such a way that their proliferation eventually provides a permanent epithelial coverage Using a technique based on similar considerations, Jackson [5] has successfully treated a large number of severely burned patients by the primary application of homografts and autografts in alternating strips

Read before the 10th Clinical Meeting of the American Medical Association, Seattle, Nov 29, 1956

Chronic Burn Wounds

Scattered stamp-like grafts of the patient's own skin may be used to obtain wound closure in the large chronic burns that are occasionally seen in children These patients, who represent serious therapeutic failures, may present themselves months after their thermal injury in a very debilitated condition

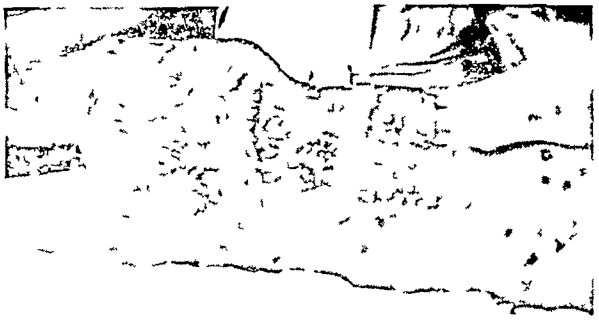

Fig 5 (case 2) —Large granulating wounds of back and left thigh are present seven months after severe burn There is evidence of attempt to obtain healing by pinch grafts Scars in interscapular region indicate donor site for pinch grafts

The wounds in such cases are characterized by unhealthy, soft, exuberant granulations and show the profuse purulent discharges which typify established infections In many cases, spontaneous healing reactions already may have produced scar contractures affecting important joints, and pressure sores are common

An aggressive two-way plan of management is indicated in these patients General measures to improve nutrition and combat infection must be pushed vigorously At the same time, the open wound must be covered with skin at the earliest possible moment

When donor areas are limited, the use of scattered stamp-like dermatome grafts may represent the best solution of the skin-coverage problem It is essential to prepare the chronic open wound carefully, however, before skin grafts are applied The application, with pressure, of dressings of fine mesh gauze impregnated with a bland ointment is usually effective in producing in a short time a wound environment which is favorable to skin grafting The edematous granulations flatten out, becoming firm and more vascular, and wound discharges diminish

After wound closure has been effected by the application of stamp-like dermatome grafts, months may be required for epithelial stabilization and the softening of associated scar tissue Residual functional defects are usually corrected by standard plastic surgical procedures at a late date, when these children are in good general condition and when only ordinary surgical risks are involved

Report of Cases

The following case reports illustrate the use of free stamp-like dermatome grafts in the management of acute and chronic wounds resulting from severe burns

Case 1 —The patient, a female aged 5 years suffered an extensive burn when her nightgown caught fire from an open fireplace A third-degree burn involved the entire back, the buttocks, the right side of the chest, and most of the neck (fig 1), second degree and third-degree burns involved more than 50% of the right upper extremity and the right thigh Careful supportive treatment, including the administration of dextrose, electrolytes, serum albumin, and whole blood through a cannula inserted by cut-down in an ankle vein carried the patient through the initial period of shock

Coverage of the large burn wound was subsequently accomplished by the staged application of stamp like dermatome grafts (fig 2) Dressings were changed at four to six day intervals in the operating room, with the patient under general anesthesia, and five skin grafts were performed Antibiotics were administered on a prophylactic basis Combiotic, a combination of penicillin and dihydrostreptomycin was used first and later tetracycline (Tetracyn) Wound infection did not develop Healing was obtained in eight weeks

The patient has had secondary insertions of large sheet like dermatome grafts to control contracture tendencies on the right side of the neck and in the right axilla At present after eight months there is no serious functional difficulty (fig 3) The right upper extremity and the right side of the neck are involved by hypertrophic scars, however Further reconstructive operations appear advisable in this case in order to obtain the best possible result as regards function and appearance Donor sites are abundant since there is minimal scarring of the original stamp graft donor areas on the left side of the chest abdomen and thighs (fig 4) no grafts were cut from the left arm and shoulder or from other sites which cannot be covered by ordinary clothing

enzymes to facilitate debridement would seem unnecessary in most cases While a few deep sloughs will separate slowly and tend to hang on, most of the wound is rapidly cleared of devitalized tissue and is soon ready to receive split-thickness skin grafts Skin grafts taken by the Reese dermatome, when left on their rubber backing, are readily cut up into pieces of postage stamp size, or larger, and distributed over denuded areas The free grafts are held in place solely by pressure dressings and may be expected to show good 'takes' when their rubber backing is removed after four or five days Since the small grafts present many edges for epithelial proliferation, maximal skin coverage is secured by each operative procedure

All dressings are changed and grafts applied with the patient under general anesthesia It is believed that in the child patient the psychological benefits to be derived from the avoidance of pain in dressing changes far outweigh the theoretical disadvantages of multiple anesthetizations

With the use of these techniques and with initiation of grafting operations as soon as skin sloughs begin to separate, wound coverage in the severely burned child can be accomplished within a reasonably short time When granulations form, these are kept flat and firm by compression dressings, and stamp grafts may be applied successfully on this heathy base without further preparation Staging of the operative procedures provides a wide margin of safety Each operation should require only a brief anesthetization, and there should be little blood loss

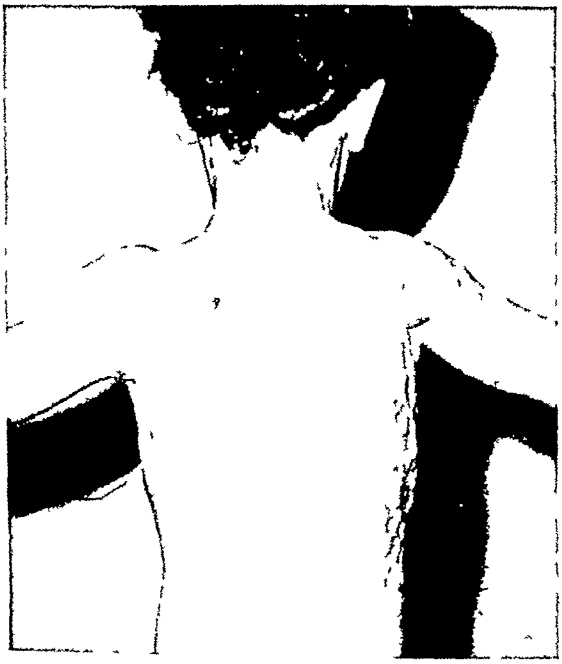

Fig 3 (case 1)—Eight months after burn stamp grafts on back and neck show excellent function

In conjunction with the treatment of the local wound, measures are taken to maintain the patient in a state of good general nutrition If the nourishment taken voluntarily is insufficient, supplementary tube feedings are employed Transfusions of whole blood are given to replace elements lost through exudates, and broad-spectrum antibiotics may be administered to prevent sepsis or the development of infection in tissues imediately involved by the burn

It is true that the skin coverage secured by the use of free stamp-like grafts may be somewhat deficient from the cosmetic standpoint These grafts have shown excellent late function, however, when they have been applied to plane surfaces of the body Since each split-graft segment carries a substantial dermal substratum, the ultimate development of a high degree of functional resiliency in grafted areas may be expected

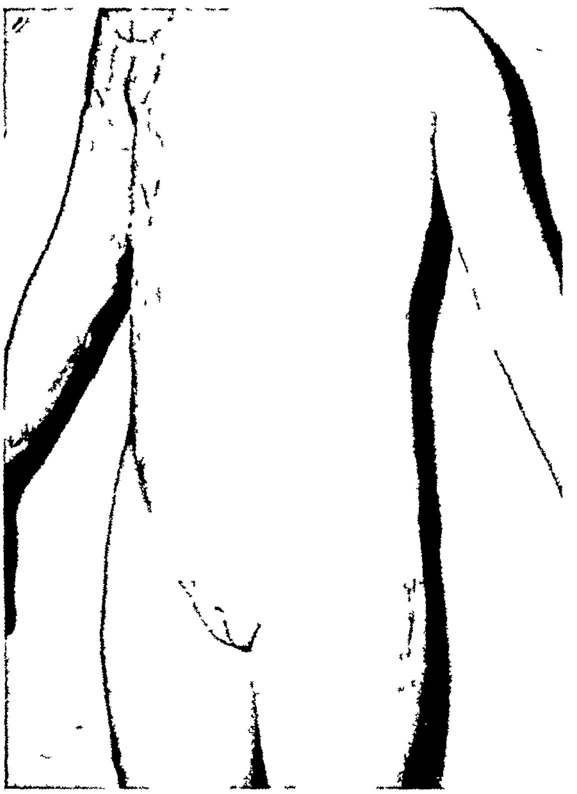

Fig 4 (case 1)—Eight months after burn donor sites on abdomen, chest (below left nipple) entire left thigh, and inner surface of right thigh show minimal scarring and may be used again to supply skin for reconstructive purposes All donor sites are covered by ordinary clothing

When feasible, relatively thick sheet-like dermatome grafts should be applied as early as possible in situations in which crippling scar contractures are prone to develop Early and complete skin coverage is very desirable in wounds involving the face, neck axillas and groins and the popliteal and antecubital regions If, in spite of all preventive efforts, serious joint contractures occur, these may be corrected by secondary operations Final satisfactory results may be secured by further insertions of larger dermatome grafts or by the use of Z-plasties, the shifting of skin flaps or the free transfer of full-thickness skin grafts The fact that the original dermatome grafts are cut at a depth of 0 01 in or less allows additional 'crops of skin to be taken as necessary from the available donor areas

On the basis of experimental findings, Najarian and McCorkle[6] have recently suggested the use of a suspension of skin particles, a so-called skin milk shake, to obtain rapid healing of large third-degree burn wounds. The value of this technique has yet to be determined in actual practice. It is expected, however, that the skin coverage supplied by the method will be most applicable as a biological dressing to prevent sepsis in severely burned patients. It is probable that little or no dermal pad will develop as the wounds heal, and secondary reconstructions with the use of sheet-like autogenous split grafts will probably be necessary in most locations for optimum function.

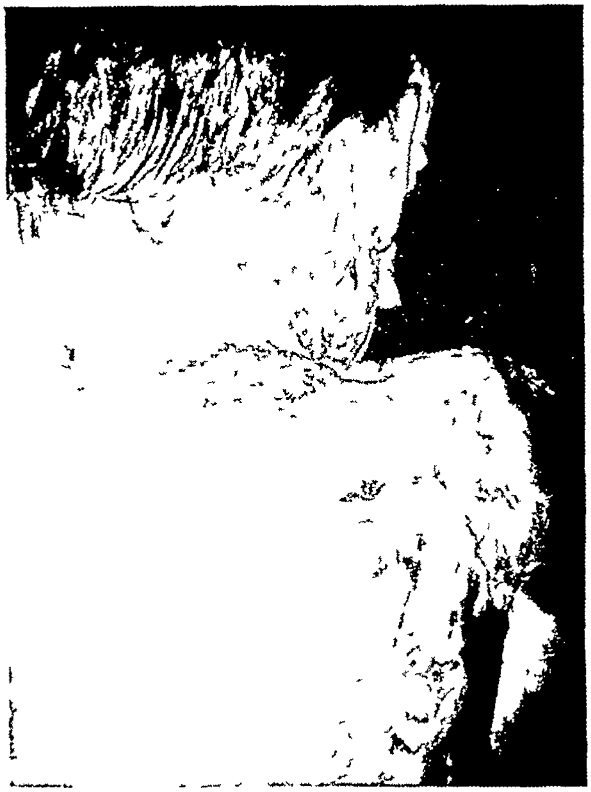

Fig. 1 (case 1).—Third degree burns of back and neck; skin sloughs are beginning to separate two weeks after severe burn.

Segmented Dermatome Grafts

One clinically proved method of supplying definitive skin coverage in extensive burns depends on the primary application of autogenous dermatome grafts in relatively small rectangular segments. These grafts are scattered over the wound, do not require suture, and have been described variously in the literature as "stamp" or "patch"[8] grafts. The principle of the technique is not new, having been introduced by Goode in 1935,[9] but the method has been greatly facilitated by recent refinements in the techniques of cutting and handling thin skin grafts.

Small skin patches have been found to "take" more surely on recently denuded and granulating surfaces than large sheets of skin, and they are relatively insusceptible to the effects of infection and hematoma formation. Stamp-like dermatome grafts are particularly efficacious in supplying skin coverage in severely burned children when the wound resulting from a deep thermal injury is very large and available donor skin is limited. If applied to a burn wound in small free pieces, these grafts may exhibit an appreciable loss of normal skin tension and show a troublesome tendency to curl and roll in. Dermatome grafts which have been cemented to rayon fabric,[10] Pliofilm,[11] or the rubber-fiber backing of the Reese Dermatape,[1] however, show no tendency to contract when cut up into small segments and may be effectively applied to wound bases by ordinary pressure dressings.

Acute Burns

A definite plan of closed-wound management is followed when stamp-like dermatome grafts are to be applied in the treatment of a severe acute burn in a child. Because the full thickness of the skin is involved, and since the majority of patients show circumferential injury, there are few indications for exposure methods.

Using an aseptic technique, the surgeon usually subjects the burned areas to an initial gentle cleansing and applies a pressure dressing. The basic layer of the compression dressing is of fine mesh gauze, which may be coated lightly with a bland ointment or moistened by frequent irrigations with isotonic sodium chloride solution. Dressings of fine mesh gauze impregnated with nitrofurazone (Furacin) have proved especially useful in the management of the burn wound, since the water-soluble base of this bacteriostatic agent insures free drainage of wound exudates but does not cause unfavorable maceration of adjacent tissues.

Unless suspicion of infection suggests the need for earlier examination, the first dressing is not changed for about a week. A general débridement, in which the Brown electric dermatome is used according to the technique of Meeker and Snyder,[13] may then be carried out. Surgical debridement in stages, in connection with later dressings, is somewhat less traumatic and accomplishes the same purpose.

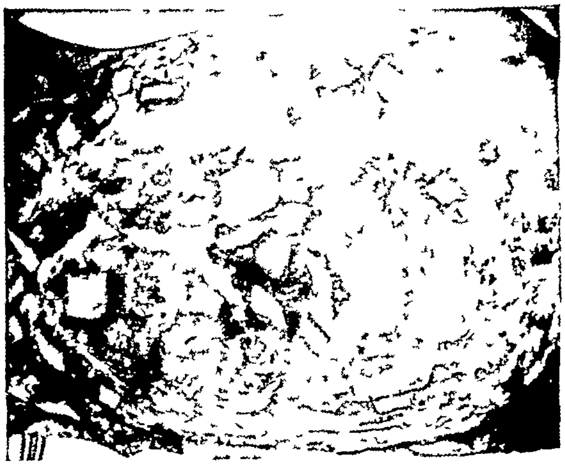

Fig. 2 (case 1).—Wounds of right side of thorax three weeks after third-degree burn. Scattered stamp grafts (Reese dermatome), applied four days earlier at first skin-grafting operation, have taken well; deep skin sloughs are still in process of separation around healthy grafts.

When compression dressings are changed at intervals of several days, the separation of sloughs is favored, and these are gently removed. The use of enzymes to facilitate débridement would seem unnecessary in most cases While a few deep sloughs will separate slowly and tend to hang on, most of the wound is rapidly cleared of devitalized tissue and is soon ready to receive split-thickness skin grafts Skin grafts taken by the Reese dermatome, when left on their rubber backing, are readily cut up into pieces of postage stamp size, or larger, and distributed over denuded areas The free grafts are held in place solely by pressure dressings and may be expected to show good takes' when their rubber backing is removed after four or five days Since the small grafts present many edges for epithelial proliferation, maximal skin coverage is secured by each operative procedure

All dressings are changed and grafts applied with the patient under general anesthesia It is believed that in the child patient the psychological benefits to be derived from the avoidance of pain in dressing changes far outweigh the theoretical disadvantages of multiple anesthetizations

With the use of these techniques and with initiation of grafting operations as soon as skin sloughs begin to separate, wound coverage in the severely burned child can be accomplished within a reasonably short time When granulations form, these are kept flat and firm by compression dressings, and stamp grafts may be applied successfully on this heathy base without further preparation Staging of the operative procedures provides a wide margin of safety Each operation should require only a brief anesthetization, and there should be little blood loss

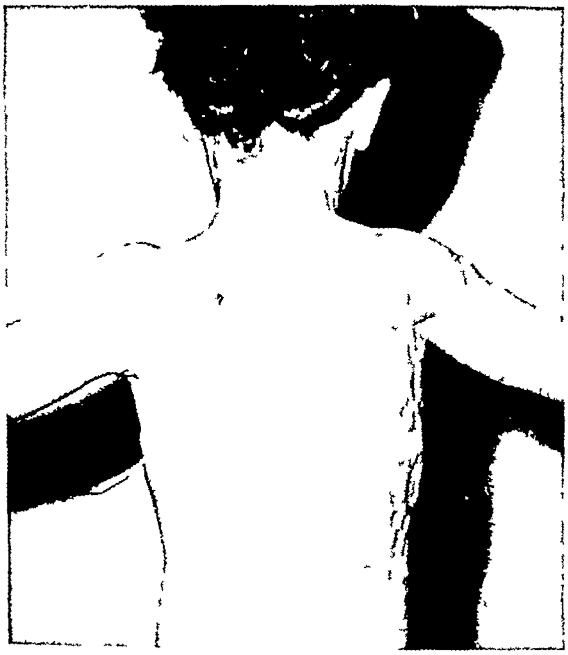

Fig 3 (case 1) —Eight months after burn stamp grafts on back and neck show excellent function

In conjunction with the treatment of the local wound, measures are taken to maintain the patient in a state of good general nutrition If the nourishment taken voluntarily is insufficient, supplementary tube feedings are employed Transfusions of whole blood are given to replace elements lost through exudates, and broad-spectrum antibiotics may be administered to prevent sepsis or the development of infection in tissues imediately involved by the burn

It is true that the skin coverage secured by the use of free stamp-like grafts may be somewhat deficient from the cosmetic standpoint These grafts have shown excellent late function, however, when they have been applied to plane surfaces of the body Since each split-graft segment carries a substantial dermal substratum the ultimate development of a high degree of functional resiliency in grafted areas may be expected

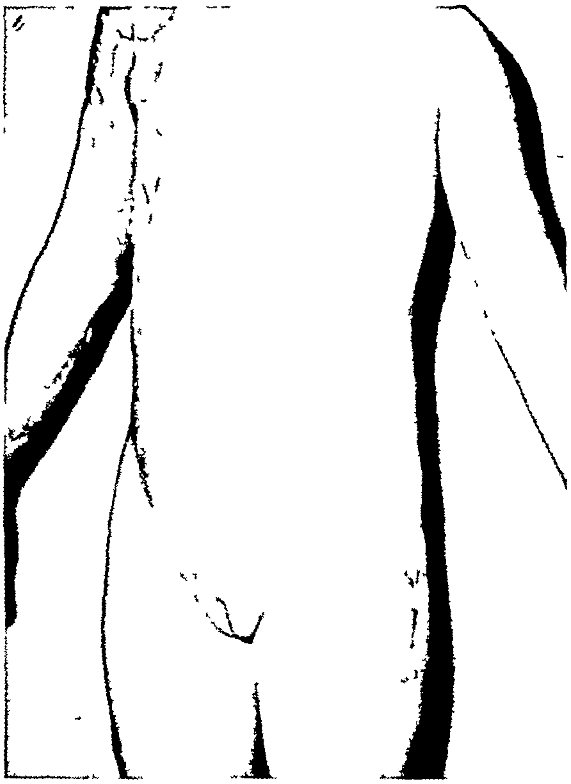

Fig 4 (case 1) —Eight months after burn donor sites on abdomen chest (below left nipple) entire left thigh, and inner surface of right thigh show minimal scarring and may be used again to supply skin for reconstructive purposes All donor sites are covered by ordinary clothing

When feasible, relatively thick sheet-like dermatome grafts should be applied as early as possible in situations in which crippling scar contractures are prone to develop Early and complete skin coverage is very desirable in wounds involving the face, neck, axillas, and groins and the popliteal and antecubital regions If in spite of all preventive efforts, serious joint contractures occur, these may be corrected by secondary operations Final satisfactory results may be secured by further insertions of larger dermatome grafts or by the use of Z-plasties, the shifting of skin flaps, or the free transfer of full-thickness skin grafts The fact that the original dermatome grafts are cut at a depth of 0 01 in or less allows additional "crops of skin to be taken as necessary from the available donor areas

Chronic Burn Wounds

Scattered stamp-like grafts of the patient's own skin may be used to obtain wound closure in the large chronic burns that are occasionally seen in children These patients, who represent serious therapeutic failures, may present themselves months after their thermal injury in a very debilitated condition

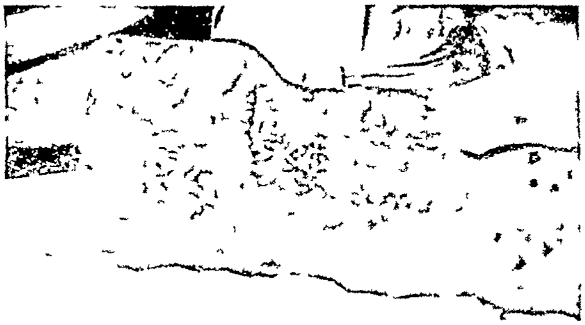

Fig 5 (case 2) —Large granulating wounds of back and left thigh are present seven months after severe burn There is evidence of attempt to obtain healing by pinch grafts Scars in interscapular region indicate donor site for pinch grafts

The wounds in such cases are characterized by unhealthy, soft, exuberant granulations and show the profuse purulent discharges which typify established infections In many cases, spontaneous healing reactions already may have produced scar contractures affecting important joints, and pressure sores are common

An aggressive two-way plan of management is indicated in these patients General measures to improve nutrition and combat infection must be pushed vigorously At the same time, the open wound must be covered with skin at the earliest possible moment

When donor areas are limited, the use of scattered stamp-like dermatome grafts may represent the best solution of the skin-coverage problem It is essential to prepare the chronic open wound carefully, however, before skin grafts are applied The application with pressure, of dressings of fine mesh gauze impregnated with a bland ointment is usually effective in producing in a short time a wound environment which is favorable to skin grafting The edematous granulations flatten out, becoming firm and more vascular, and wound discharges diminish

The application of antiseptics or antibiotic agents locally may hasten the control of infection, but it is believed that the mechanical factors involved in frequent changes of pressure dressings are most important in preparing a wound for skin grafting While the shaving down of granulations tends to improve the base for skin grafting, the blood loss involved in such operative preparation precludes its routine employment in the large wounds of this chronically ill group of patients

It is remarkable how rapidly the child patient shows improvement as skin coverage is provided for a chronic open wound which has resulted after an extensive deep burn Reduction in pain and fever and the control of tissue element depletion lead to improvement in weight, strength, and morale

After wound closure has been effected by the application of stamp-like dermatome grafts, months ma be required for epithelial stabilization and the softening of associated scar tissue Residual functional defects are usually corrected by standard plastic surgica procedures at a late date, when these children are i good general condition and when only ordinary surgical risks are involved

Report of Cases

The following case reports illustrate the use of fre stamp-like dermatome grafts in the management o acute and chronic wounds resulting from severe burns

Case 1 —The patient, a female, aged 5 years, suffered a extensive burn when her nightgown caught fire from an ope fireplace A third-degree burn involved the entire back, th buttocks, the right side of the chest, and most of the nec (fig 1) second-degree and third degree burns involved mor than 50% of the right upper extremity and the right thigh Careful supportive treatment, including the administratio of dextrose, electrolytes, serum albumin, and whole bloo through a cannula inserted by cut-down in an ankle vei carried the patient through the initial period of shock

Coverage of the large burn wound was subsequently accomplished by the staged application of stamp-like dermatom grafts (fig 2) Dressings were changed at four to six da intervals in the operating room, with the patient under gener anesthesia, and five skin grafts were performed Antibiotics wer administered on a prophylactic basis Combiotic, a combinatio of penicillin and dihydrostreptomycin, was used first, and late tetracycline (Tetracyn) Wound infection did not develop Healing was obtained in eight weeks

The patient has had secondary insertions of large sheet lik dermatome grafts to control contracture tendencies on th right side of the neck and in the right axilla At present, afte eight months, there is no serious functional difficulty (fig 3) The right upper extremity and the right side of the neck ar involved by hypertrophic scars, however Further reconstructive operations appear advisable in this case in order to obtai the best possible result as regards function and appearance Donor sites are abundant, since there is minimal scarring o the original stamp-graft donor areas on the left side of th chest, abdomen and thighs (fig 4) no grafts were cut from the left arm and shoulder or from other sites which canno be covered by ordinary clothing

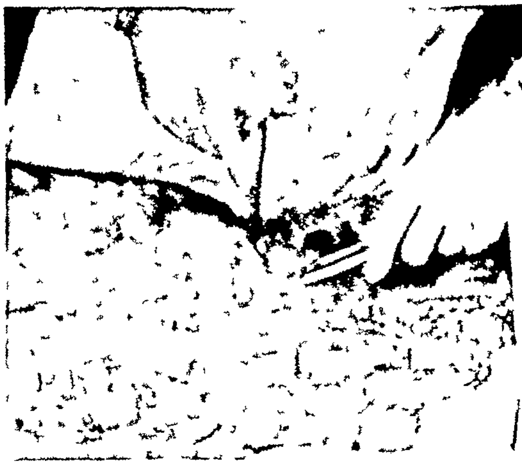

Fig 6 (case 2) —Removal of rubber backing from stam grafts five days after first grafting operation Grafts had bee cut at 0 008 in with the Reese dermatome Good "take" o grafts is evident

Case 2 —The patient, a female, aged 12 years, was first see seven months after a severe gasoline burn At this time, sh showed general depletion, and an established infection i extensive chronic burn wounds Open granulating areas wer present on the left thigh the lower back and buttocks the lower part of the chest on the left and on the abdomen red hypertrophic scars on the left arm marked the sites of spontaneous healing reactions Deep pressure sores had exposed the anterior-superior spine of the ilium on either side Pinch grafts which had been transplanted from the interscapular region to the lower back had resulted in the epithelization of only a few scattered areas

On admission to the hospital the patient showed a marked secondary anemia, with a blood hemoglobin value of 68% The temperature was of septic type with a daily elevation to 102 F (38 9 C) Wound discharges which were initially profuse were controlled by compression dressings a basic layer of fine mesh gauze impregnated with nitrofurazone being applied directly on the granulating surfaces Multiple transfusions were given to correct the hemoglobin deficiency and the patient's fever receded after the administration of antibiotics In the treatment of this patient's penicillin-resistant micrococcic (staphylococcic) infection, chloramphenicol (Chloromycetin) was first used later, chlortetracycline (Aureomycin) proved more effective

Three dressing changes with the patient under general anesthesia at four day intervals were required to prepare the wounds for skin grafting (fig 5) When the preparation of the wounds had been completed three large dermatome grafts were taken from the right thigh cut up into rectangular segments averaging 1 by 1 5 in and distributed generally over the granulating areas of back and buttocks A good take of the free skin transplants occurred (fig 6) Two weeks later similar stamp grafting of the wounds of the left side of the chest abdomen and left thigh was carried out

Because it had seemed advisable to space the grafts of the first two operations widely on the wounds secondary applications of small free grafts were required Complete skin coverage was accomplished by three additional minor skin-grafting procedures in which the right thigh and the right side of the abdomen were used as donor areas and the patient was discharged from the hospital after 10 weeks A year later full thickness skin flaps were shifted to improve the coverage of the anterior-superior iliac spine the sites of the previous pressure sores and keloids developing on the left arm were replaced by thick dermatome grafts

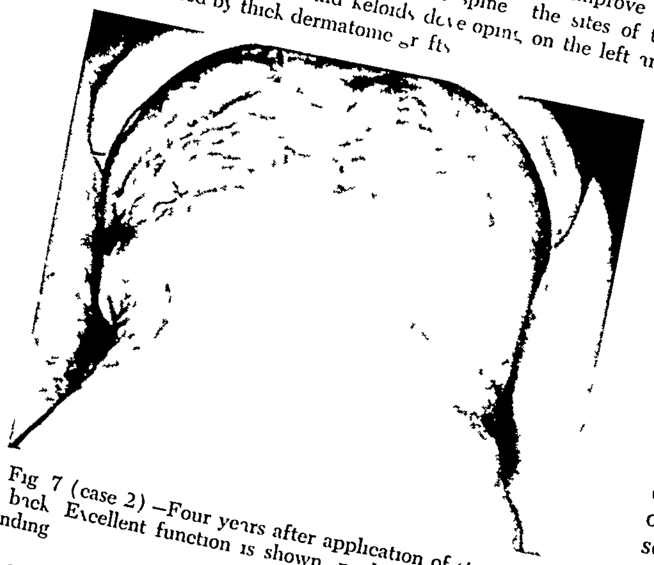

Fig 7 (case 2)—Four years after application of stamp grafts to back Excellent function is shown no limitation of forward bending

After four years this patient shows excellent function of the trunk and lower extremities (fig 7 and 8) The stamp grafts are soft and pliable and scars between the grafts show no tendency to hypertrophy There is minimal scarring of donor sites although successive crops of split-thickness grafts were taken during the course of treatment

Summary

Ideally, a large third-degree burn in a child is managed surgically by complete coverage of the wound by skin grafting as soon as devitalized tissue can be removed and a healthy base established If the skin grafts can be applied in relatively thick sheets, satisfactory function may be anticipated in most locations without further treatment

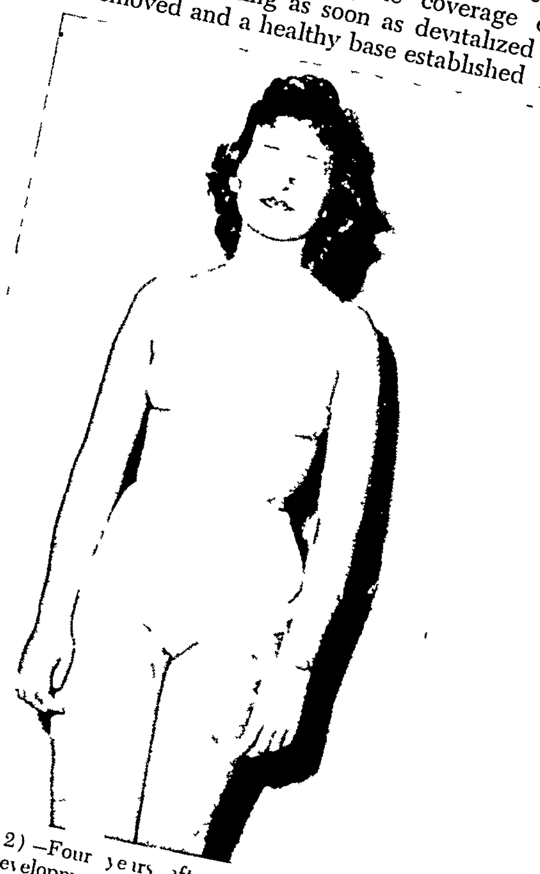

Fig 8 (case 2)—Four years after skin grafting patient shows excellent development and nutrition Grafts on left thigh function well Donor sites on right thigh and trunk were used several times they show minimal scarring however and are concealed by ordinary clothing

Management that represents a compromise with the ideal may be necessitated by the large size of the burn and a corresponding limitation of skin donor areas Brown's use of homografts from cadavers is undoubtedly of great potential value for the emergency handling of mass burn casualties The method has the disadvantage of providing a wound coverage which is temporary in nature The skin milk-shake techniques of Najarian and McCorkle, which have proved effective on an experimental basis, also will probably leave something to be desired in the treatment of individual patients

The use of free stamp-like dermatome grafts is recommended as a surgical expedient to accomplish primary wound closure in very large burns in children The skin coverage obtained by stamp-like grafts is permanent and should prove to be of generally good functional quality If late secondary contractures occur, these may be relieved by elective plastic operations of more conventional type

TREATMENT OF MILD DEPRESSIONS IN GENERAL OFFICE PRACTICE

Frederick Lemere, M D, Seattle

• Depression manifests itself in both mental and physical symptoms, some of which escape recognition unless the physician is alert The mental symptoms include not only a sad and morbid outlook but also guilt feelings, indecisiveness, loss of interest, and apprehension The physical symptoms include loss of weight and a variety of functional disorders If their nature is understood, the necessary treatment by psychotherapy, electroshock, or analeptics can be given Sedatives and tranquilizers have no beneficial effect on the depression, some aggravate it The danger of suicide must be kept in mind Depression is a most distressing illness, but the prognosis is good The patient must be encouraged by the interest and understanding of the physician There is no greater satisfaction than to see a depressed patient restored from the depths of despair to a normal, happy life

Next to anxiety-tension states, depression is the commonest type of neurosis seen in general practice A depression is primarily a mood disturbance, with many physical concomitants The physical symptoms may so dominate the clinical picture as to mask the true nature of the patient's illness The physician who is not alert to the possibility of an underlying depressive reaction may be led into many a diagnostic and therapeutic blind alley

When a depression is caused by an unhappy experience, it is called an exogenous or reactive depression When it occurs spontaneously, for no apparent or adequate reason, it is termed an endogenous depression and is considered to be a manifestation of the manic-depressive disorders It is characteristic of endogenous depressions that the patient feels worse in the morning and better in the afternoon and evening In my experience, both types of depression occur with about equal frequency, and, of course, many patients present a mixture of exogenous and endogenous factors

Clinical Diagnosis

In many cases, the diagnosis of a depression will be obvious from the patient's own statements and demeanor In many other cases, however, the depressive nature of the illness will not be recognized by either the patient or the doctor unless the latter judiciously questions the patient for the typical symptoms of this disorder These symptoms may be divided into physical and mental

Mental Symptoms—The mental symptoms may be grouped into five divisions 1 Depressed spirits The patient has a morbid, hopeless outlook, with crying spells and suicidal ideas 2 Guilt feelings The patient blames himself for everything and feels inferior, inadequate, and unworthy He thinks himself a failure and broods over imagined or minor mistakes 3 Difficulty in concentrating The patient is absent-minded, cannot make decisions, cannot read, and fears he is losing his mind 4 Loss of interest The patient has no zest or enthusiasm He neglects himself and his work and has to make himself do things 5 Apprehension The patient has exaggerated fears and worries about everything, especially the future The depression may not be the presenting symptom, as is demonstrated by the following cases

Case 1—A 33-year-old housewife wanted to place her children in a home and divorce her husband because of a false feeling of failure as a wife and mother Recognition of the underlying depression and consequent successful treatment prevented a marital tragedy

---

From the Department of Psychiatry, University of Washington School of Medicine

Read before the 10th Clinical Meeting of the American Medical Association Seattle Nov 27, 1956

CASE 2—A 46-year old salesman literally worried himself sick over having improperly listed a $5 nonbusiness expense as tax deductible His exaggerated feelings of guilt and hopelessness over the situation made the diagnosis of depression obvious

CASE 3—A 56 year-old housewife, for no apparent reason insisted on selling her home after many happy years and purchased another house She disliked the new house and became critically ill when she was unable to buy back her old home The initial dissatisfaction and subsequent indecision made the diagnosis and treatment of depression possible

Physical Symptoms—The physical symptoms may be grouped into four divisions 1 Loss of appetite and weight Food nauseates the patient He has a coated tongue and suffers from constipation and flatulence He has usually lost 20 or 30 lb (8 or 12 kg) in weight 2 Insomnia The patient's insomnia is often severe and intractable 3 Fatigue The patient, whose fatigue is often worse in the morning, wakes up feeling more tired than when he went to bed Often this feeling of fatigue is greater than that produced by organic illness 4 Nervous tension Nervous tension is especially pronounced in agitated or tension depressions and in multiple psychosomatic complaints

The physical symptoms of depression may be more prominent than the mental symptoms, as illustrated by the following causes

CASE 4—A 26 year-old schoolteacher had her teeth pulled and her facial nerve injected several times before it was recognized that the pain in her face and jaws was due to a depression After an attempted suicide she was given electroshock treatments with relief from the pain and the depression

CASE 5—A 45 year old steelworker was treated for 10 months for sexual impotency urinary frequency and bladder pain without apparent organic basis After it had been elicited that he had feelings of depression with crying spells the true diagnosis was finally established

Treatment

Unfortunately, no drug has been developed that will satisfactorily relieve depression Such stimulants as the amphetamines (dextro amphetamine [Dexedrine] sulfate and methamphetamine [Desoxyn, Methedrine] hydrochloride), pipradrol (Meratron) hydrochloride, and methylphenidate (Ritalin) hydrochloride are the most helpful and often give some measure of relief in mild cases At best, however, they leave much to be desired from the standpoint of sustained adequate elevation of mood

Sedatives and tranquilizers may bring some relief for the often associated tension and anxiety, but they have no effect whatsoever on the depression Reserpine, and perhaps chlorpromazine hydrochloride, may even aggravate the depression Combinations of stimulants and sedatives or tranquilizers, such as Dexamyl (dextro amphetamine and amobarbital) or Thoradex (chlorpromazine and dextro amphetamine), are usually more effective than either alone Sedatives for sleep at night and vitamins and frequent, small, high-calorie feedings for maintenance of nutrition are usually indicated

Because of the relative inadequacy of drugs, the main attack on this disease still has to be psychotherapeutic In the treatment of reactive depressions, the comforting encouragement, the understanding sympathy, and the wise advice of a trusted physician are most helpful This, plus the healing passage of time, will see most patients through their illness Even when nothing can be done about a continued hopeless situation, the opportunity to unburden himself to his doctor often brings the patient moral support and the courage to carry on

Psychotherapy of the spontaneous or endogenous depressions hinges on the fact that depressive attacks are usually self-limited Almost all of these patients will recover within a few months' to a year's time, regardless of the type of treatment used Although some depressed patients will have one or more subsequent attacks during their lifetime, the prognosis for any given attack is excellent The physician must seize on this favorable prognosis to assure the patient that his condition is temporary and that he will get well

Constant, emphatic, and authoritative assurances of eventual recovery must be impressed on the patient, otherwise he may not have the courage to fight through what is perhaps the most painful of all illnesses Suicide is the great risk in depressions, and often the patient's faith in his doctor's promise that he will again be well and happy is the only thing that will keep him from ending his life The physician should warn the relatives about the possibility of suicide, so that such things as guns or large amounts of sedatives may be kept away from the patient The physician should never, of course, write a prescription that would make a lethal amount of a sedative available to a depressed patient unless a relative will take responsibility for handling the medicament Although no one can accurately predict which patients will attempt suicide, the opinions of relatives will often be helpful in this respect Suspected imminence of suicide or a depression lasting longer than nine months are indications for electroshock treatment Electroshock is the most effective therapy available for severe endogenous depressions and may be lifesaving

Most depressed people have an exaggerated sense of guilt The physician should take advantage of this to discuss these feelings as well as any other personal problems that the patient may be prompted to bring up for discussion Because he already feels unworthy, admonitions to the patient that he could get well if he wanted to and exhortations to increased activity only serve to drive him deeper into his depression Continued patient encouragement is the best help anyone can give a depressed person

Because of the morbid thoughts and the difficulty in concentrating or making decisions, many depressed patients fear that they will become insane They can be reassured on this score by the explanation that this illness is an emotional and not a mental disorder and that they will not lose control of their faculties

It should also be explained to the patient that recovery from a depression is an up-and-down proposition rather than a smoothly progressive convalescence such as usually occurs with organic disease More and more "good" days and fewer and fewer "bad" days are experienced, until finally all the days are "good" days again Unless a patient understands this, he is apt to feel he has slipped back to where he started from when he has a "bad" day Because of this, he may lose heart and his progress be delayed

Many patients will ask how long they are going to be ill Inasmuch as it is impossible to foretell with any certainty the duration of a depression, it is best not to commit oneself on this I tell most patients that no one can say just how long they will be ill but that with nervous exhaustion it usually takes several months before the nervous system can be built up to the point where they will feel like their normal selves again

Conclusions

Although depression is one of the most distressing illnesses that a doctor is called upon to treat, it may be one of the most rewarding Because the illness is usually self-limiting, almost all depressed patients will eventually recover If the doctor has been patient and understanding enough to see the patient through his ordeal he, the doctor, will get the credit for the cure There can be no more grateful patient or relatives, nor is there any greater satisfaction than to see a patient restored from the depths of despair to a normal happy life Most people who are subject to depression are, when well, some of the finest, warmest, and most conscientious and productive people in the community

BRONCHOGRAPHY IN THE DIAGNOSIS OF PEDIATRIC PROBLEMS

Charles F Ferguson, M D
and
Carlyle G Flake, M D, Boston

• *Exact and early diagnosis of bronchopulmonary abnormalities in children is important because some conditions formerly irremediable can now be corrected surgically Tracheoesophageal fistula, for example, can and should be repaired before chronic pneumonitis develops Diagnosis of tracheoesphageal fistula without esophageal atresia by endoscopic means alone is difficult, but it is rendered easier and more precise by combining bronchoscopy and bronchography under general anesthesia in the technique here outlined In bronchography for other conditions, iodized oil is injected by catheter through an endotracheal tube under fluoroscopic control, and each lobe is filled as the patient is turned into various positions After the desired roentgenograms have been obtained, the oil is removed by aspiration The causation of stridor, persistent atelectasis, and other abnormalities may thus be explained Recent advances in intrathoracic surgery, especially about the aortic arch, have made it possible to eradicate the cause of the symptoms in many such cases*

In recent years bronchography has become increasingly useful in the solution of many perplexing bronchopulmonary problems of infancy and childhood Early, accurate diagnosis is of the greatest importance if the patient is to receive maximum benefit from the progress which has taken place in the field of pediatric thoracic and cardiovascular surgery

The clinical symptoms which should alert the physician to the probable need for a more thorough chest examination than can be accomplished by the stethoscope and routine roentgenographic studies alone are (1) chronic pulmonary changes which can be demonstrated by the usual roentgenographic studies, (2) unexplained chronic cough, whether productive or nonproductive, (3) stridor, which is often erroneously presumed to be laryngeal in origin, (4) recurring infection in the same area of the lung, (5) persistent or recurring wheezing emanating from the same area of the lung, and (6) hemoptysis (not, in our experience, commonly observed in childhood, but, when seen, usually associated with severe pulmonary pathology)

The medical management of chronic pulmonary infection is greatly facilitated by bronchography It not only assists in the establishment of a correct diagnosis and indicates the extent of the disease but also records the clinical courses of such patients to determine the efficacy of treatment by the different antibiotic agents

Bronchiectasis

Bronchiectasis has always been considered a serious disease in childhood yet today many patients are being treated successfully by medical therapy alone Before such treatment is undertaken, an accurate evaluation of the condition of the tracheobronchial tree should be carried out In our opinion, in addition to the usual roentgenographic studies, this evaluation should include careful bronchoscopy, bacteriological and fungus studies of the pulmonary secretions, with sensitivity tests, and bronchography

While all of the factors in the etiology of bronchiectasis are not known, most observers are agreed that the pathological changes noted are chiefly the result of prolonged bronchial obstruction plus infection In childhood, bronchiectasis is often preceded or accompanied by a number of conditions in which these factors are prominent features Among the more common conditions are unresolved pneumonia (fig 1), persistent atelectasis (particularly that involving the middle lobe), pertussis, recurrent attacks of bronchitis and sinusitis, and severe asthma Less common causes, in our experience, have been mucoviscidosis (fibrocystic disease of the pancreas) (fig 2 *A*), foreign-body aspiration (fig 2 *B*), and stenosis of a bronchus In such

Read before the Section on Laryngology, Otology and Rhinology at the 104th Annual Meeting of the American Medical Association, Atlantic City, N J June 8, 1955

From the departments of otolaryngology Childrens' Medical Center and Harvard Medical School instances, however, the bronchiectasis may be very severe Anomalies of the tracheobronchial tree occur with much greater frequency than has been generally suspected in the past[1] We have observed bronchiectasis associated with various anomalies, including those of the right upper lobe bronchus where the bronchus arises from the trachea just above the bifurcation and is often twisted or partially stenosed Congenital stenosis of a normally situated bronchus has been noted on several occasions Weakness, severe malformation, or even absence of bronchial cartilages have been observed in the main bronchi of young patients with bronchiectasis Thus, whenever the factors of infection and obstruction are found as a chronic condition, bronchiectasis is commonly seen

Agenesis of the Lung

An infant or young child who presents signs of dulness, whose breath sounds are absent, and who may or may not have displacement of the mediastinum recognized clinically or roentgenographically may be suspected of having unresolved pneumonia or atelectasis On occasions, such findings may indicate agenesis of the lung, and in such instances bronchography is of great assistance in establishing a correct diagnosis[1] In most cases this condition is relatively asymptomatic, so that the pediatrician should be aware of the possibility of such an anomaly when he is confronted with an abnormality of the lung field that is not completely satisfactorily explained otherwise

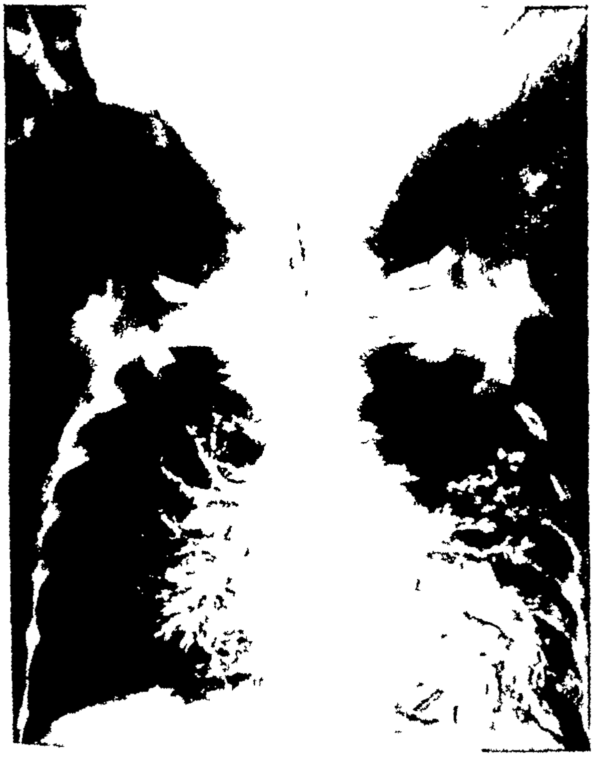

Fig 1—Bronchiectasis of left lung after unresolved pneumonia (anteroposterior view) Marked saccular dilatation is apparent in lower lobe

Other multiple congenital defects are usually associated with agenesis of the lung, and they may serve to arouse suspicion of the proper diagnosis

Agenesis of the lung may be of three types (1) true aplasia, with no trace of lung, bronchus, or vascular supply, (2) tiny outpocketing, or bud of the trachea, with no lung tissue, and (3) extreme hypoplasia of the bronchus, with no true lung tissue (fig 3)

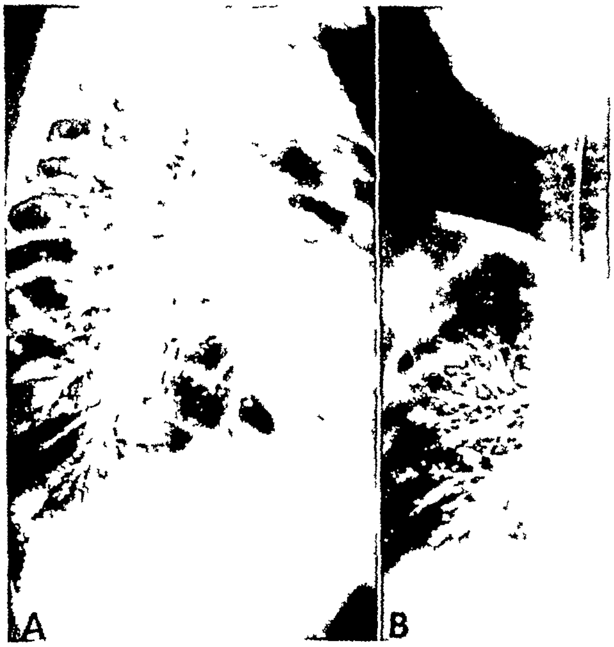

Fig 2—*A*, generalized bronchiectasis associated with mucoviscidosis (oblique view with right bronchus injected) *B*, bronchiectasis of right lower lobe after aspiration of timothy grass—top (anteroposterior view)

Tracheoesophageal Fistula

Tracheoesophageal fistula is an important congenital anomaly that is frequently observed at large pediatric centers, yet it may be difficult to recognize In most cases, the fistula is associated with atresia of the esophagus, and difficulties will be obvious from the first attempt at feeding The diagnosis should be made promptly However, in patients where the esophagus is patent, a tracheoesophageal fistula may give no symptoms except recurrent attacks of pneumonitis of the aspiration type[2] Choking on liquids rather than solid food, in a person with or without persistent loose cough, may arouse suspicion, but usually it is not until later in infancy or childhood that the correct diagnosis is made In such cases, bronchography may be of great help in delineating the fistula if it has not already been demonstrated fluoroscopically by means of swallowing of a contrast medium It is very difficult to visualize such a fistula endoscopically, even with the Broyles telescope Early diagnosis is important, so that the fistula can be repaired surgically before the development of chronic pneumonitis with resultant fibrosis or bronchiectasis (fig 4)

Stridor

Stridor is an extremely common condition in infancy, and in the past the larynx was regarded as the usual site of its origin. Now we know it is by no means the only one. Stridor must be regarded as merely a symptom, and its cause must be adequately determined in each case. In the presence of a normal larynx the true cause of the stridor may be found only by careful evaluation of the tracheobronchial tree. Bronchoscopic examination may show a true stenosis of the trachea, which is indistinguishable roentgenographically from an apparent narrowing due to a glottic obstruction. In the latter case, the narrowing is present only during the phase of inspiration and will disappear when the glottis is held open by an anterior-commissure laryngoscope. Thus it is a transient physiological obstruction and not due to a fixed anatomic narrowing. Abnormalities of the epiglottis or of the arytenoepiglottic folds are usually responsible for this condition. If the cartilaginous framework of the trachea is deficient, local collapse of a segment of the trachea or bronchus will occur during each respiratory cycle. Stridor, dyspnea, or even cyanosis may result, along with intercostal, suprasternal, and infrasternal retraction. This may be seen endoscopically and recorded graphically by serial tracheograms or bronchograms. By the use of special equipment, 15 to 20 films may be exposed in rapid succession during several respiratory cycles. The abnormal area can be seen to change its caliber if there is a local deficiency of the tracheal cartilages.

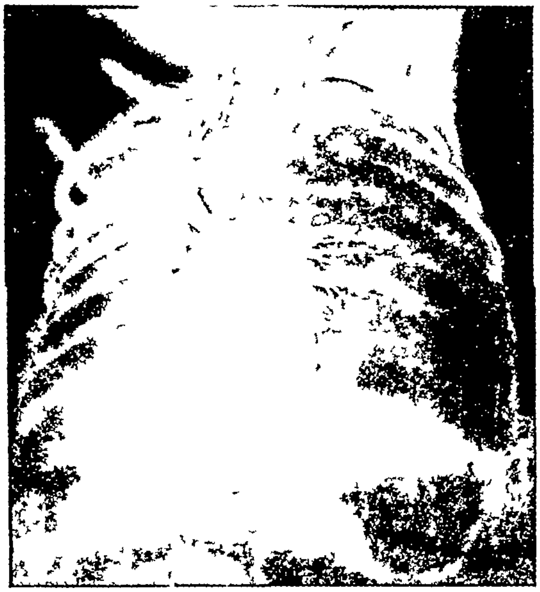

Fig 3.—Agenesis of right lung (anteroposterior view)

By far, the commonest extralaryngeal causes of stridor are to be found, however, in patients who have a compression of the trachea by an abnormal aortic arch, with or without malformation of the great vessels.[3] The earliest and most severe symptoms of tracheal obstruction and stridor are usually seen in infants who have a double aortic arch, the commonest type of vascular ring. In such cases, both the right and left fourth embryonic arches persist and encircle the trachea and esophagus. This usually produces symptoms of a distressing type before the infant is 6 months of age. These babies have severe respiratory embarrassment, stridor which is both inspiratory and expiratory in phase, dyspnea, wheezing, retractions, and attacks of cyanosis. Dysphagia is common, or more often merely a 'hesitation' in swallowing is noted. Bronchoscopic examination of such infants reveals a compression of the lower portion of the trachea at the level of the third or fourth thoracic vertebra, and, as visualized by barium studies, the esophagus is also constricted at this same level (fig 5). In the absence of a mediastinal mass, such a picture of constriction of both the trachea and esophagus at the same level is pathognomonic of some type of vascular ring. Today, successful division of such a ring can be carried out by a competent thoracic surgeon, giving complete relief of the infant's symptoms.[4] The diagnosis, however, must be made as early as possible, before permanent damage is done to the already constricted and badly deformed cartilages.

Similar symptoms may be produced by another type of ring, due to a right-sided aortic arch with a constricting ligamentum arteriosum. Such patients will usually live for 12 to 18 months before symptoms become apparent. The time when symptoms appear, however, will depend on the length and tightness of the ligamentum. The ligamentum is the remains of the ductus arteriosus, which connects the pulmonary ar-

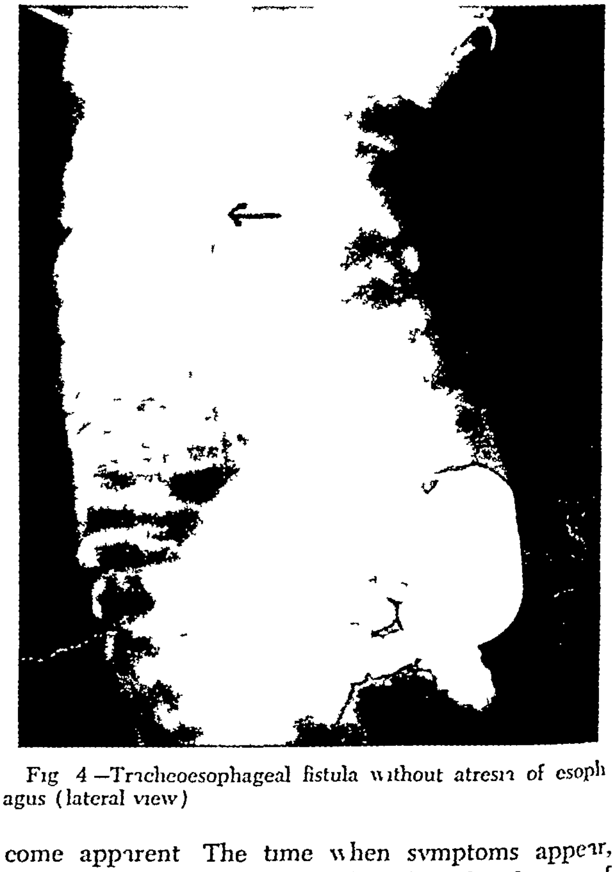

Fig 4.—Tracheoesophageal fistula without atresia of esophagus (lateral view)

tery anteriorly to the first portion of the aorta posteriorly Therefore, if the arch of the aorta is placed on the right side, the ductus arteriosus (or ligamentum) must of necessity curve around the left side of the trachea and esophagus and, in most instances, posterior to it This completes a constricting ring In such cases the left subclavian artery may run posterior to the esophagus and cause additional compression Anomalies of the innominate artery or left common carotid artery may cause an anterior compression of the tracheal wall with resultant stridor and signs of obstruction *Here, however, there are no esophageal* symptoms, and barium studies of the esophagus show an adequate lumen throughout Such conditions will result if the innominate artery arises too far to the left *on the aortic arch or if the left common carotid arises* too far to the right, thereby crossing the trachea anteriorly Each of these defects can be corrected surgically and the compression relieved

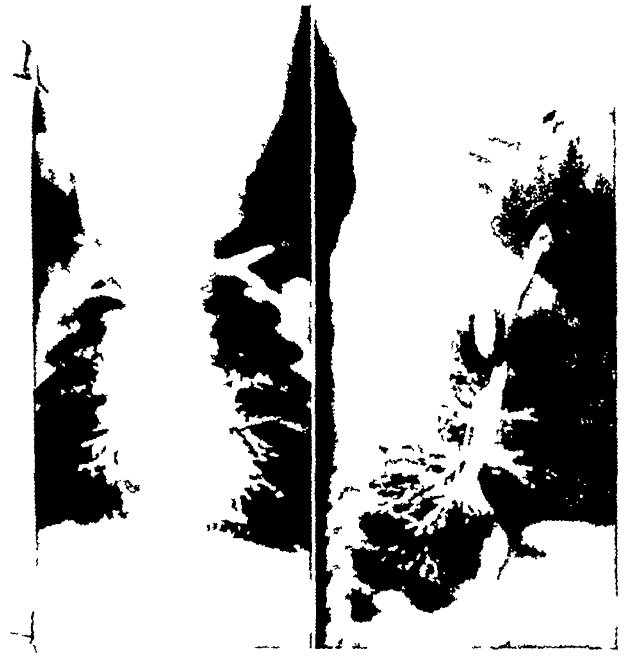

Fig 5 —Double aortic arch *Left*, anteroposterior view Constriction of both trachea and esophagus at same level is shown *Right*, lateral view showing pinchcock effect of compression ring

Technique

At the Children s Medical Center in Boston most of our tracheographic and bronchographic studies are performed with the patient under general anesthesia This technique has been described in more detail elsewhere [5] Premedication with pentobarbital (Nembutal) and atropine is followed by the administration of vinyl ether (Vinethene) and ether anesthesia, using the open mask method On occasion, in older children, basal anesthesia with rectally given tribromoethanol (Avertin) is used *instead of pentobarbital premedication* A complete bronchoscopic examination is made, during which secretions are aspirated into a Lukens tube, for bacteriological and fungus cultures Sensitivity tests against the various antibiotic agents *are always carried* out After completion of the bronchoscopic procedure, an endotracheal tube is inserted Under fluoroscopic control, iodized oil (Lipiodol) is injected via a polyethylene catheter inserted through the endotracheal tube Each lobe *is filled under direct vision, as the* patient is turned into various positions When satisfactory filling has been completed, five routine views are obtained (namely, an anteroposterior, a lateral, and three oblique views) The oil is then aspirated and the *endotracheal tube removed* The amount of oil employed varies with the size of the patient From 1 to 2 cc is used in a small infant when it is desired to outline only the trachea It may be necessary to use *15 to 20 cc in an older child with bronchiectasis The patient should be kept at just the right stage of anesthesia*, so that the cough reflex will be suppressed for three or four minutes to allow the films to be completed Teamwork, involving the anesthesiologist, the radiologist and his technician, and the endoscopist, is essential for satisfactory results

Summary

Bronchographic studies are necessary for accurate diagnosis of many bronchopulmonary problems in infants and children Such studies are especially helpful in determining the presence and degree of bronchiectasis and are also of great value in recording and *evaluating progress during medical treatment* Bronchiectasis is usually associated with a number of conditions in which the factors of infection and obstruction are the most prominent features The possibilities of agenesis of the lung and tracheoesophageal fistula without esophageal atresia should be considered in patients with abnormal pulmonary findings Stridor, usually considered as emanating from the larynx alone, may be due to stenosis of the trachea, to external compression of the trachea, or to stenosis of a main bronchus It is especially severe in patients who have anomalies of the aortic arch or great vessels that produce external tracheal compression This type of anomaly is now amenable to surgery

MECHANISM OF INFLAMMATION AS RELATED TO SURGICAL MANAGEMENT AND GENERAL RESISTANCE

William P Herbst, Washington, D C

• Three cases involving elderly patients are described to illustrate the effectiveness of orally administered corticoids in increasing general resistance to recurrent infections and to surgical shock An 85 year old man who had gone into profound shock after catheterization subsequently underwent the first and second stages of suprapubic prostatectomy without reactions with the help of maintenance doses of cortisone A 78 year old man went into profound shock after the third of a series of operations, but was maintained on doses of hydrocortisone not exceeding 50 mg per day until death resulted from the rupture of an aortic aneurysm A 50 year old woman had been hospitalized repeatedly for recurring pyelonephritis unaffected by antibiotics and chemotherapy, recurrences stopped when cortisone was administered in doses of 2 5 mg daily by mouth Antibiotics and chemotherapy should always be used along with corticoid medication, and their use should be continued for a time after corticoid medication has been stopped It is important to adjust the dosage of corticoids so as to avoid the gastrointestinal necrosis, delayed healing, and upset of electrolyte balance that have been reported after the use of large doses

Advanced knowledge in the field of homeostasis as related to general resistance, shock, the general adaptation syndrome and the mechanism of inflammation has resulted in the saving of many lives which would otherwise have been lost The problem of general resistance as related to frequently recurring pyelonephritis and cystitis is another field in which basic biochemical factors related to inflammation afford principles which may be constructively utilized

Homeostasis is defined by Cannon as "Maintenance of steady states by coordinated physiological processes" [1] The maintenance of steady states involves the environment and the sum total influence of individual cell metabolism Shock, although very complex, exerts its chief destructive effects through anoxia and will be discussed only in connection with the maintenance of satisfactory blood pressure levels The general adaptation syndrome, as described by Selye,[2] has provided one of the most satisfactory explanatory schemes of clinical phenomena that anyone has presented in recent times Exhaustion is frequently synonymous with death The contraction of the heart muscle is supposed to depend on the presence of a lipid steroid chemical substance related chemically to toad venom [3]

Clinical Management

The first International Symposium on the Mechanism of Inflammation was held in conjunction with the 19th International Physiological Congress in September, 1953 at Montreal Canada Instead of extensive reference to the transaction of this conference, a few of the pertinent observations which have clinical management potentialities will be presented

Ungar [4] presented a schematic representation involving the fibrinolytic mechanism which indicates that histamine elaborated in a stage of proteolysis produces (1) vasodilation, (2) stasis, and (3) increased vascular permeability This presentation, as well as the contributions of Carson and Campbell,[5] Duran-Reynals,[6] Judd and Henderson,[7] Kindall and Nickels,[8] Mayer and Kull [9] Rich and Lewis,[10] and me,[11] provides the rationale behind the clinical use of antihistamines in acute infectious inflammatory lesions

Menkin [12] studied the effect of anti-inflammatory substances on isolated cellular systems He used the ova of the sea urchin Keeping them in sea water with a small amount of cortisone for 15 minutes and then fertilizing them brought about cell division Variations in incidence of cleavage were used as an indication of variations in cell activity Cortisone hydrocortisone, and corticotropin produced a depressing effect Somatotropic hormone did not

Taubenhaus [13] observed that somatotropic hormone, thyroxin and desoxycorticosterone stimulated granulation tissue and that cortisone, hydrocortisone, estrogen, testosterone, and methylandrostenediol inhibited granulation tissue He also observed that methantheline bromide (Banthine) and Dibenamine (N, N-dibenzyl beta-chloroethylamine hydrochloride) have an inhibiting effect on granulation tissue similar to some of the corticosteroids

There are many other observations in the "Mechanism of Inflammation" for which space will not permit further reference I suggest that a reading of this book is most rewarding

Report of Cases

In the field of general resistance we are confronted with the problem of how to make infrequent the incidence of such recurring acute infectious entities as pyelonephritis and cystitis

We know very little about resistance except that it is considered to be low after exhaustion, emotional shock, chilling, and wetting and when the hemoglobin level or red blood cell count is low The possible relationship of steroids to general resistance is important and will be referred to later

Three clinical cases illustrative of general resistance follow

Case 1 —An 85 year-old man had experienced recurring pyuria with fever, frequency, urgency, and varying amounts of residual urine for more than a year and had refused any surgical intervention On May 30 1955 he gave a history of recent hematuria chills pains in the penis, and inability to void He

---

From the Department of Urology Georgetown University Medical School

Read before the Section on Urology at the 105th Annual Meeting of the American Medical Association, Chicago June 12 1956 was hospitalized and catheterization produced 160 cc of bloody infected urine His temperature rose to 105 F (40 6 C) in less than an hour The blood pressure dropped to 70 mm Hg He was in profound shock

He was started immediately on therapy with levarterenol (Levophed) bitartrate in distilled water, in addition, 500 mg of tetracycline (Achromycin) and 50 mg of hydrocortisone were given intravenously The levarterenol administration was continued periodically for three days because his blood pressure would not stay up Cortisone was given orally 25 mg twice a day until June 8 1955 on which day suprapubic cystostomy was performed without incident On June 14 a second stage prostatectomy was carried out The patient had no reaction to the operation

He left the hospital on the 10th postoperative day During his convalescence he was at first given 25 mg of cortisone a day and then was placed on maintenance therapy with 10 mg a day when he left the hospital the maintenance dosage was reduced to 5 mg a day In conjunction with this he was given antibiotics continuously and very important they were continued after the cortisone was withdrawn[14]

Case 2—A 78 year old poor risk male had had a very narrow escape from death after biliary surgery He had developed an obstruction in the neck of the bladder and an indwelling catheter was necessary during the three month postoperative period He was to undergo a suprapubic prostatectomy whenever he was considered sufficiently recovered to do so However the incision for such surgery revealed a peculiar hemorrhagic blood factor which made it unwise to proceed Blood studies failed to disclose the reason for this bleeding problem Vitamin B_1 in doses of 100 mcg daily was given for the week after the cystostomy on the basis of previous observations that such therapy seems to be helpful in certain bleeding problems

A second stage suprapubic prostatectomy was carried out one week after the cystostomy and no untoward incident occurred during surgery The patient did have an unusually large gland and because of his previous bleeding experience the capsule was packed with iodoform gauze for hemostasis He got along very satisfactorily from the prostatectomy However after the removal of the packing on the fifth postoperative day his blood pressure went down to practically nothing and he suffered profound shock and had to be immediately resuscitated with oxygen and intravenous doses of levarterenol He was given blood transfusions 50 mg of hydrocortisone and intravenous doses of tetracycline and penicillin He was given 25 mg of diphenhydramine (Benadryl) hydrochloride by hypodermic injection

After this initial episode which demanded levarterenol for four days his electrolytic balance was continuously all right and he was on maintenance therapy with antibiotics vitamins and blood given intravenously He was critically ill for three weeks with one week of total unconsciousness On numerous occasions the nurses felt that it was not possible for him to survive another hour He regained consciousness however and appeared to be well on the road to recovery when an aortic aneurysm ruptured and resulted in instant death An autopsy demonstrated that he had had multiple miliary renal abscesses bilaterally, which were in various stages of resolution The dosage of hydrocortisone had not exceeded 50 mg per day nor more than 25 mg of diphenhydramine when that was given The last week the dose had been tapered off to 25 mg of cortisone orally

Case 3—A 50 year old woman was often hospitalized for prolonged frequently recurring pyelonephritis She was seen in consultation in the hospital in an acute pyelonephritic attack in September, 1944 From 1944 until April 1953 she was hospitalized with recurrence of these acute, febrile bilateral pyelonephritis and cystitic problems because of the inability to control the infection with the customary supportive chemotherapeutic vitamin and antibiotic therapy

Upon discharge on April 28, 1953, she was put on therapy with cortisone, 2 5 mg orally daily On May 15, 1953, she reported that she was feeling fine and gaining weight By June 15 1953 she had gained 5 lb (2 3 kg) From that date until February, 1956 at which time she moved to California, she took cortisone 2 5 mg per day, whenever she felt herself "slipping She would take it from periods of anywhere from one week to six weeks at a time

Use of Antihistamines and Corticoids

There are certain aspects concerning the use of antihistamines and corticoids that should be discussed Very important is the fact that antibiotics or chemotherapeutic agents should always be used along with corticoids[13] This is not important in the administration of antihistamines[11a]

The dosage to be used is very important, because much larger doses than are necessary or advisable are very frequently used and because small doses, meaning doses from 1 to 25 mg of any of the corticoids, do not influence the electrolytic balance to any appreciable degree There has been considerable comment on the production of perforating gastrointestinal ulcers after the administration of the corticoids These accidents do occur but they occur in the patients who are given large doses of from 50 to 300 mg per day

There is also the criticism of interference with healing In the surgical procedures carried out for bilateral adrenalectomy, really large doses of cortisone are given preoperatively and postoperatively with no difficulty in wound healing There should be no reason for anyone's not realizing that large dosages, that is, over 50 mg per day, would almost certainly upset homeostasis and possibly unfavorably so In addition, it is noteworthy that 1 mg of estradioldipropionate produced a most spectacular clinical response the first time it was used in the treatment of advanced metastatic carcinoma[15] It is unreasonable to feel that 5 mg of any corticoid would seriously upset homeostatic balances

In regard to antihistamines, tripelennamine (Pyribenzamine) hydrochloride has been used in doses of 50 mg one to three times a day Diphenhydramine is given in 25 mg doses orally or by injection from one to three times a day

It is noteworthy that many anesthetists use diphenhydramine and hydrocortisone by injection[16] both during the operation and in the early postoperative recovery period For patients who have frequently recurring infectious inflammatory lesions of the urinary tract, doses of the corticoids vary anywhere from 1 mg of prednisolone to 2 5 mg of cortisone without any untoward reaction The reports that one receives of the patients own observations of the influence of these small doses of cortisone are very impressive Recently I saw a patient who had been on therapy with 1 mg of prednisolone for a month after dismissal from the hospital for an acute pyelonephritis and cystitis attack She stated that for the whole month that she took the prednisolone she felt fine and that when the drug was withdrawn she did not feel nearly so well and that, moreover, two months later she had mild recurrence of cystitis

Summary

There are available spectacularly effective pharmaceutical agents which successfully prevent death in conditions of severe shock, acute infectious inflammatory lesions, and general resistance deficiencies Whenever corticoids are administered, antibiotics or chemotherapeutic agents should be administered along with them and their administration continued after the

Fifteen days postoperatively, the patient no longer had hypesthesia in her left hand Five months later she had more strength in her hand, and there was less atrophy of the thenar muscles A little more than one year postoperatively, atrophy of the thenar muscles had disappeared and there was a complete return of normal strength in the left thumb It is now almost two years since this patient's operation, and she has had no further trouble with her hand

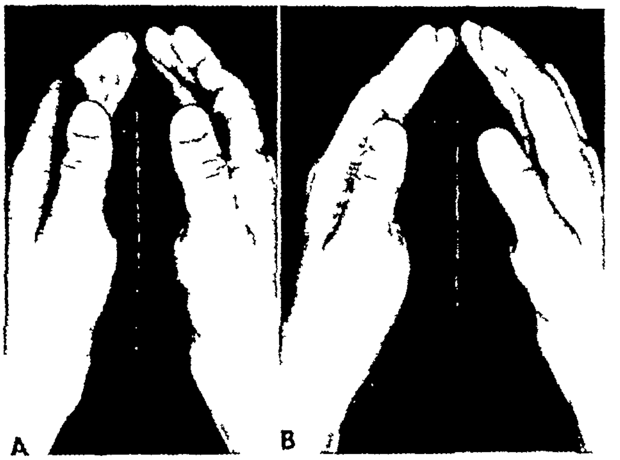

Fig 3 (case 2) —A, lateral view of hands, showing bilateral atrophy of thenar muscles more pronounced in right hand B, lateral view of both hands three months after decompression of median nerve at left wrist, showing return to normal of thenar muscles in left hand

Case 2 —A 38 year-old woman was first examined here on July 6 1954 She had noticed slight pain in the thumb and index and middle fingers of her right hand about 10 years previously There was no history of injury Three years before examination, she developed numbness in the median distribution of her right hand, together with a slight flexion deformity of all fingers She consulted a neurosurgeon who made a diagnosis of compression neuropathy of the median nerve in the carpal tunnel In September, 1951, the right wrist was operated on, with section of the transverse carpal ligament and neurolysis of the median nerve The flexion contracture of the fingers and some of the pain in her hand were relieved after this operation but the numbness continued to increase in severity, and she still had much pain in her hand at night During the year before examination here there had been a gradual atrophy of the thenar muscles In March 1954, four months before examination, she first noticed pain and numbness in the median distribution of the left hand These symptoms had gradually increased in severity so that she had great difficulty in buttoning her clothes or doing any sort of work with her hands During the two months before examination, she had observed a gradual wasting of the thenar muscles accompanied by extreme weakness in her thumb She frequently had cut and burned her fingers without realizing it She had noticed a slight swelling on the volar aspect of each wrist for the past several months

Examination of the right hand revealed extreme hypesthesia in the median distribution with pronounced atrophy of all the thenar muscles supplied by the median nerve Grip in the hand was weak The wrist flexion test was negative and Tinel's sign was weakly present over the median nerve at the wrist There was a soft nontender, subcutaneous swelling over the flexor tendons just proximal to the wrist joint There was a well-healed longitudinal operative scar 4 5 cm in length, extending across the wrist joint and volar aspect of the forearm Results of examination of the left hand were essentially the same as those in the right except that the hypesthesia in the median distribution and the thenar atrophy were not quite as pronounced (fig 3A)

On Aug 7 1954 the left wrist was operated upon The flexor synovialis was found to be greatly hypertrophic and densely adherent to the flexor tendons There was a bulbous swelling of the median nerve proximal to the edge of the transverse carpal ligament, and the nerve was severely compressed within the carpal tunnel The transverse carpal ligament was sectioned, and the major portion of the thickened flexor synovialis was excised The median nerve was adequately decompressed by this procedure Ten days postoperatively, the patient noticed some return of sensation in the median distribution of her hand She no longer had any pain in her hand Eleven weeks postoperatively, she lacked sensation only in the tips of the index and middle fingers and the thenar muscle atrophy was disappearing

The patient requested that another operation be performed on her right wrist On Dec 9, 1954, a 7-cm incision was made transversely across the wrist for a short distance and then continued down the center of the forearm, excising the previous incisional scar The palmaris longus tendon was found to be pressing firmly down into the substance of the median nerve, this tendon was excised The median nerve was found to be flattened and moderately indurated The normal median nerve at a point 6 cm from the distal flexor crease at the wrist measured 6 mm in diameter The nerve then ballooned out to 12 mm in diameter as it passed into the carpal tunnel (fig 4) The nerve was also compressed in the carpal tunnel The flexor synovialis was thickened and had to be separated by sharp dissection from the flexor tendons It was necessary to excise the major portion of this flexor synovialis to decompress the median nerve Three weeks after the second operation the patient noticed slight improvement in sensation in her right hand, and she also experienced some twitching in the paralyzed thumb muscles Six months later there was further return of sensation in the hand but no evidence of improvement in the thenar atrophy

At the present time, the patient has normal sensation in her left hand and normal power in the thumb muscles Sensation is diminished in the tips of the thumb and index and middle fingers of the right hand and there still is moderate atrophy of the thenar muscles (fig 3B) Biopsy specimens of the flexor synovialis from each wrist revealed a microscopic picture compatible with rheumatoid synovitis The synovial lining cells were hypertrophic and there were focal collections of lymphocytes (fig 5)

Case 3 —A 55 year-old man was first examined here on Nov 30, 1954 For three years prior to examination the patient had recurrent attacks of severe pain and tingling in the median distribution of his right hand There was no history of any injury to the wrist, but each attack seemed to follow excessive use of his hand In the past year he had observed some wasting away of the thenar muscles and had noticed that the paresthesias in his hand became more severe when he was writing Between the acute attacks there remained some hypesthesia in the median distribution in the hand

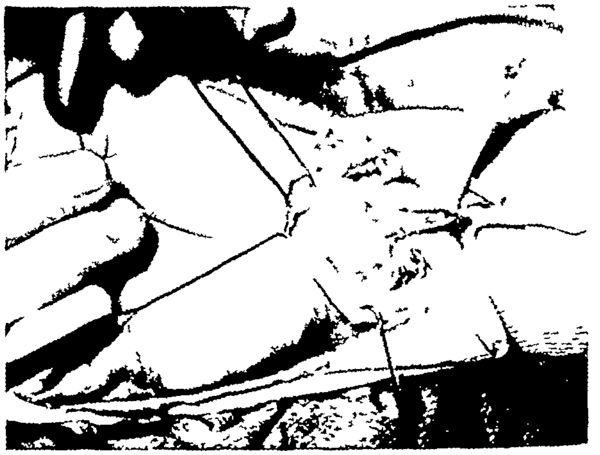

Fig 4 (case 2) —Photograph showing findings at operation on right wrist Palmaris longus tendon has been sectioned at its insertion and turned backward onto forearm Rubber drain has been passed beneath normal median nerve in forearm Note how median nerve is swollen proximal to transverse carpal ligament due to pronounced hypertrophy of underlying flexor synovialis

Examination revealed that Tinel's sign over the median nerve at the wrist was present, a positive wrist flexion test, mild hypesthesia in the median distribution distal to the wrist joint and moderate thenar atrophy, involving principally the short flexor and short abductor muscles A roentgenogram of the wrist revealed no abnormality

On Dec 30, 1951, the transverse carpal ligament was sectioned through a transverse incision in the distal flexion crease at the wrist There was a definite bulbous swelling of the nerve proximal to the edge of the transverse carpal ligament The palmaris longus tendon was excised because it appeared to have been exerting considerable pressure on the underlying median nerve The flexor synovialis was moderately thickened A biopsy of this synovialis revealed evidence of chronic nonspecific inflammation

The day after operation, the patient said that he no longer had the thorns in the end of the fingers that he had had prior to the operation especially at night When the patient was last seen in May, 1956, he had no symptoms referable to either hand and the thenar atrophy had disappeared

Diagnosis

The diagnosis of spontaneous compression of the median nerve in the carpal tunnel must be considered when a patient complains of hypesthesia or paresthesias in the median distribution or when there is isolated paralysis of the thenar muscles supplied by the median nerve The history is usually that of a progressive weakness and clumsiness in the hands, associated with numbness and tingling in the median distribution distal to the wrist joint Although occasionally there may be some aching or pain radiating up the forearm and even up to the shoulder, there never are any objective sensory changes proximal to the wrist joint

In none of the 71 patients in this series was there a history of injury We have seen two cases in which the carpal tunnel syndrome developed many years after fractures about the wrist, these cases of tardy median palsy are not included in this series

In patients with bilateral compression neuropathy, the symptoms were more severe in the dominant hand Strenuous use of the hand always seemed to aggravate the pain and numbness in the median distribution, although the patient sometimes was not aware of this until after resting the hand for several hours after the manual activity Many patients also complained of pain at night, which frequently was severe enough to prevent sleep Although the hypesthesia was slight in some cases at the time of testing, the patient would readily point out the portion of the hand in which paresthesias and numbness occurred after strenuous use of the hand, and this area invariably coincided with the sensory distribution of the median nerve

Hypesthesia in the median distribution was the most constant of all clinical findings in this series, occurring in 68 (96%) of the 71 patients Tinel's sign is a tingling sensation radiating out into the hand, obtained by light percussion over the median nerve at the wrist Tinel's sign was present in 63 (89%) of the 71 patients

Atrophy of the thenar muscles—opponens, short flexor, and short abductor muscles—was observed in varying degrees in 38 (54%) of the 71 patients Some of these patients were unaware of this atrophy until it was brought to their attention On looking down on the palm of the hand, one may often fail to observe the thenar atrophy, which is readily apparent when the profiles of the two thumbs are compared (fig 2) If the opponens muscle is spared, there may be pronounced atrophy of the thenar muscles without significant weakness in the thumb It has been established that there may be marked anatomic variation in the innervation of the thenar muscles, the ulnar nerve may supply some or all of the thenar muscles that usually are supplied by the median nerve[9]

The so called wrist flexion test was a very helpful diagnostic aid The patient is asked to flex both wrists completely and keep them flexed for approximately 60 seconds In this position, the median nerve is pressed upon by the proximal edge of the transverse carpal ligament to a greater extent than it is when the wrist is extended Even in the normal wrist, prolonged complete flexion of the wrist will eventually cause numbness in the median distribution in the hand In cases of compression neuropathy of the median nerve, however, there usually is a prompt exacerbation of numbness and paresthesias in the median distribution in the hand when the wrist is held in a flexed position, with prompt improvement in these symptoms when the wrist is returned to a neutral position The wrist flexion test was positive in 57 (73%) of the 71 patients

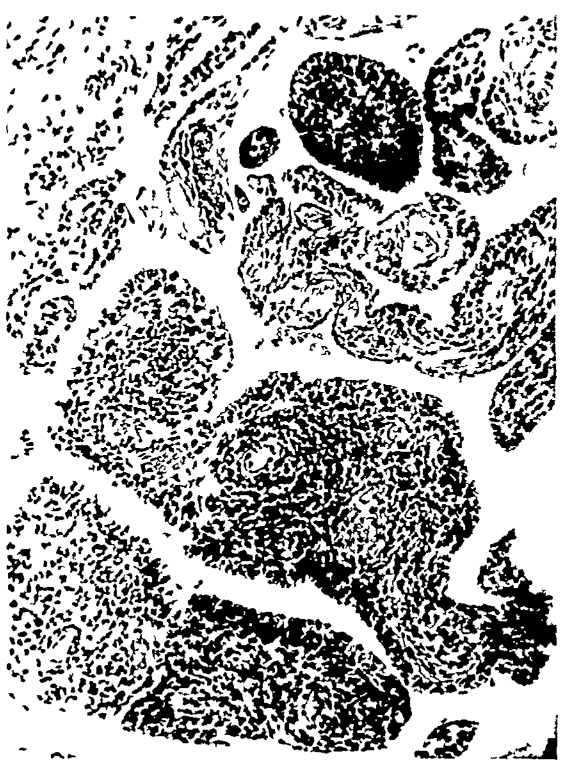

Fig 5 (case 2) —Photomicrograph of flexor synovialis showing hypertrophy of synovial lining cells and focal collections of lymphocytes compatible with microscopic findings in rheumatoid synovitis

It has been shown experimentally that pressure within the carpal tunnel is increased by extension of the wrist Sustained extension of the wrist, therefore, may also produce an exacerbation of numbness and tingling in the median distribution However, we have found that the wrist extension test is only occasionally positive in these cases and is not a reliable diagnostic sign

A pneumatic-tourniquet test has been described by Gilliatt and Wilson [7] Increased pain and paresthesias in the median distribution is produced by inflating a pneumatic cuff above the systolic pressure on the arm of patients with a carpal tunnel syndrome The test was positive in 13 of a series of 35 patients with compression neuropathy of the median nerve In many of our more recent cases we have employed this test, but we believe it is not so reliable as the wrist flexion test

Roentgenograms were made of at least one wrist in each patient in this series In no case was there evidence of sufficient arthritis or bony abnormality to produce the patient's symptoms of median nerve compression Special carpal tunnel views were not made in every case, so we cannot comment specifically about the bony contour of the carpal tunnel Since none of the patients in this series had a history of injury to the wrist or hand, one would not anticipate the presence of structural abnormalities in the distal radius or the carpus

If there is sufficient thickening of the flexor synovialis, there may be obvious swelling or a palpable thickening over the volar aspect of the forearm proximal to the wrist joint On two occasions, the median nerve itself was palpable as a firm, very tender subcutaneous mass immediately proximal to the transverse carpal ligament This mass was mistaken for a ganglion preoperatively in one case, this case has been previously reported by one of us [8]

In the 71 patients, the duration of symptoms referable to the hands was less than 6 months in 17 patients, from 6 months to 2 years in 23, from 2 years to 10 years in 19, from 10 years to 15 years in 8, from 15 years to 25 years in 3, and more than 25 years in 1 It is interesting to note that only 17 (24%) of the patients had had symptoms in their hands for six months or less The great majority of the patients had had complaints referable to their hands for at least a year or more Two patients had had symptoms for 20 years, one for 25 years, and another for 30 years

Differential Diagnosis

Pain and hypesthesia in the fingers can be produced by any lesion involving the nerve pathways to the hand Lesions of the central nervous system, such as brain tumors, syringomyelia, or degenerative diseases of the spinal cord, sometimes are causative Much more frequently, however, the lesion is found to be one that produces irritation of the fifth to eighth cervical nerve roots, such as protruded cervical intervertebral disks, hypertrophic arthritis of the cervical spine, and injuries involving the cervical nerve roots The peripheral nerves, including the brachial plexus, may be the site of the trouble A tumor or aneurysm in the neck, a cervical rib, or a tight anterior scalene muscle may compress the trunks of the brachial plexus The symptoms in the hands may be only a part of a generalized polyneuritis or a diabetic neuropathy

All of these conditions must be considered in the differential diagnosis of the carpal tunnel syndrome An accurate diagnosis of compression neuropathy of the median nerve in the carpal tunnel may be made, however, if Tinel's sign is present over the median nerve at the wrist, a wrist flexion test is positive, and all objective sensory findings are strictly limited to the median distribution distal to the wrist These are the three most reliable and most constant findings, and in almost every case at least two of these three clinical findings are present In addition, there will be partial atrophy of the thenar muscles in more than half of the cases

Pathogenesis

From our experience in the observation and treatment of these 71 patients, we have concluded that spontaneous compression of the median nerve in the carpal tunnel is caused by thickening of the flexor synovialis within the carpal tunnel The exact etiology of this condition could not be determined Biopsy specimens of the flexor synovialis were taken from 38 of the 49 wrists operated upon, and 14 of these biopsies showed evidence of a chronic inflammation compatible with a diagnosis of rheumatoid synovitis The other 24 biopsies revealed only a fibrosis or thickening of the synovialis without definite evidence of any inflammatory changes Sections were also made of the transverse carpal ligament in some of the patients, but no evidence of inflammation was seen in any of these specimens

Edema and thickening of the flexor synovialis seem to us to be the most likely cause of the development of a spontaneous compression of the median nerve in the carpal tunnel Nissen [1d] has also found a chronic nonspecific proliferative tenosynovitis about the flexor tendons in his cases We believe this tenosynovitis must be fundamentally rheumatic in origin, although it is certainly not necessarily associated with true rheumatoid arthritis The improvement noted in some cases after the injection of hydrocortisone (Hydrocortone) into the carpal tunnel would also lend credence to the rheumatic nature of the tenosynovitis Furthermore many of the patients complained of some periarticular swelling and transient stiffness in the small joints of the hand these symptoms were believed to result from a periarthritis

Ischemia of the median nerve has been cited as the primary cause of this spontaneous compression neuropathy [1c] Certainly, compression of the nerve may result in a certain degree of ischemia and this ischemia may, in turn, play some role in the production of the clinical syndrome The rapid disappearance of paresthesias and pain after operation makes it reasonable to regard the lesion as a transient ischemia of the nerve, but we believe this ischemia must be secondary to the thickening of the flexor synovialis rather than a primary condition

We believe that spontaneous compression neuropathy of the median nerve in the carpal tunnel is not an occupational disease Often repeated, forceful grasping movements might cause some tenosynovitis of the flexor tendons in the carpal tunnel, but this certainly is not a common finding External pressure, of course, from a hard object over a long period of time might also cause some direct pressure on the median nerve Kendall [1e] believes that the principal factor in the production of the carpal tunnel syndrome is a compression of the median nerve by muscle action It is true that almost every patient in our series described an aggravation of symptoms after strenuous use of the hands, and the symptoms were almost always worse in the dominant hand None of these patients, however, consistently did an excessive amount of work with the hands

The carpal tunnel syndrome has been described in association with certain systemic disorders, such as acromegaly and pleonosteosis,[9] which are usually accompanied by various degrees of proliferation of fibrous tissue There was no evidence of these systemic disorders in any of our cases

It is interesting to speculate why spontaneous compression of the median nerve occurs so much more frequently in women than in men There is no structural difference in the carpal tunnels of men and of women Men certainly subject their hands to more trauma than do women It is a well-known clinical observation, however, that rheumatic conditions of various types about the wrist and hand are more common in women than in men In this present series of cases, there was one woman with an associated Quervain's disease (stenosing tenosynovitis of the long abductor and short extensor tendons of the thumb), four women had an associated 'trigger finger (stenosing tenosynovitis of the flexor tendons in the palm), one woman had an acute pisiform bursitis, and two women had a 'tennis elbow (lateral humeral epicondylitis)

Since the majority of patients with compression neuropathy of the median nerve are women in menopause, Schiller and Kolb[11] have suggested that there may be a stimulation of connective tissue growth when estrogens are no longer present to suppress the activity of pituitary growth hormone They have treated three patients with so-called menopausal median neuropathy by the administration of estrogens in each patient the digital pain disappeared We have not used this treatment in any of our cases, but other authors[10] state that treatment with estrogens is not effective

Treatment

Decompression of the median nerve may be readily accomplished by section of the transverse carpal ligament This operation is recommended only when the patient's symptoms are severe and of long duration or when there is evidence of progression of the numbness and paresthesias in the fingers or evidence of thenar atrophy

The operation can be readily performed with the aid of local anesthesia, but we prefer to employ a general anesthetic, which permits a more thorough exploration of the median nerve and carpal tunnel A bloodless field, obtained by use of a pneumatic tourniquet, greatly facilitates the operation

A 3 cm transverse incision is made in the distal flexion crease of the wrist The medial end of this incision may be continued up the forearm, and the lateral end of the incision may be continued into the palm, forming an S-shaped incision through which the entire carpal tunnel and the lower forearm may be exposed We have seldom found it necessary, however, to employ so long an incision The simple transverse incision usually provides sufficient exposure to permit section of the transverse carpal ligament Care must be taken to section the entire ligament along its medial aspect in order to avoid any possible damage to the recurrent branch of the median nerve

A simple sectioning of the tranverse carpal ligament is usually sufficient to decompress the median nerve However, it sometimes is necessary to do a partial synovectomy before adequate decompression of the nerve can be obtained Synovectomy was done in 3 of the 49 procedures in this series

Since there has been no evidence of any disability whatsoever from section of the transverse carpal ligament, no patient should be denied the benefit of operation if there are positive indications for surgical treatment as noted above Not all patients with spontaneous compression of the median nerve in the carpal tunnel require surgery If the symptoms are mild and of short duration, a period of rest for the hand, with use of a simple wrist splint, may cause all symptoms to disappear The administration of hydrocortisone also may result in improvement

In this series we have operated upon 49 wrists in 37 patients Twelve patients with bilateral symptoms had only one wrist operated upon Eleven other patients with bilateral symptoms had only one wrist operated upon, symptoms in the other hand not being sufficiently severe to require surgical treatment We preferred not to operate upon both wrists at the same time, only two patients insisted that this be done One wrist was operated upon twice because the transverse carpal ligament was not completely severed at the first operation

Results of Treatment

The results in all 49 wrists that were surgically treated were good as far as relief from pain was concerned Not infrequently, on the day after the operation, the patients would volunteer the information that they no longer had the paresthesias and night pain that they used to have Normal sensation returned in 32 hands, and the remaining 17 hands regained some sensation in varying degrees

Thirty of the hands that were operated on had evidence of thenar atrophy Thirteen of these hands regained normal size and strength in their thenar muscles within from 6 to 12 months after the operation Eight of the 30 hands showed no evidence of regeneration of the thenar muscles, but none of these became worse The remaining nine hands showed varying degrees of improvement The thenar muscles improved the quickest, of course, in those hands in which the muscles had been paralyzed the shortest time preoperatively As a general rule, if the paralysis had existed for more than one year, the outlook for recovery after decompression of the median nerve was not too good However, two patients who had had atrophy for more than three years regained normal thenar muscles after the operation

Fifty per cent of the wrists that were operated upon showed a definite bulbous swelling of the median nerve proximal to the edge of the transverse carpal ligament In no case was there evidence of a true interstitial neuroma It was not necessary to perform a neurolysis of the median nerve in any case

At operation the median nerve showed evidence of obvious compression by the transverse carpal ligament in 60% of the cases In some there was a definite groove in the nerve where it rested beneath the proximal edge of the transverse carpal ligament We realize that there is normally a certain degree of flattening of the median nerve as it passes through the carpal tunnel

At operation 70% of the wrists showed definite evidence of a thickening of the flexor synovialis that we believe was sufficient to account for the median nerve compression

Five cases were reported as showing no obvious abnormality at the time of operation However, all of these patients were promptly relieved of their symptoms after sectioning of the transverse carpal ligament

In 20 of our more recent cases we have employed injections of hydrocortisone into the carpal tunnel, and 16 of these patients have shown definite improvement Usually three or four injections of 1 cc at weekly intervals are sufficient, and several patients required only a single injection for relief The injection is made by inserting a 25-gauge needle directly into the carpal tunnel, passing just medial to the palmaris longus tendon and the median nerve The 1 cc of hydrocortisone is dispersed among the flexor tendons and beneath the median nerve in the carpal tunnel No discomfort is experienced by the patient during the injection

Summary

We examined 71 patients with spontaneous compression of the median nerve in the carpal tunnel Most of these patients were women between the ages of 40 and 60 years We believe that in most, if not all, of these cases the condition was caused by some type of localized rheumatic disease—most often a chronic nonspecific proliferative tenosynovitis of the flexor tendons Diagnosis of this condition is made on the basis of a positive wrist flexion test, the presence of Tinel s sign over the median nerve at the wrist, and the limitation of all sensory findings to the median distribution distal to the wrist The majority of the patients in this series also had evidence of partial thenar atrophy The patient's symptoms of pain and paresthesias in the median distribution of the hand may be readily relieved by sectioning the transverse carpal ligament to decompress the median nerve in the carpal tunnel Only rarely is a partial synovectomy also necessary to decompress the nerve adequately In some cases surgery is not necessary, a simple wrist splint or the administration of hydrocortisone may alleviate the symptoms

Periodic Peritonitis —American pediatric literature and textbooks do not contain any reports of periodic peritonitis, a syndrome which is familiar to internists in this country as well as physicians in the Near East and North Africa This disease, often familial, apparently is limited principally to Arabs, Armenians, and Jews, but other peoples occasionally are affected Periodic peritonitis is characterized by abdominal pain and tenderness, fever, polymorphonuclear leucocytosis, and, at times, pain in the thorax and joints The duration of an attack is 24 to 72 hours, it is followed by complete remission, but exacerbations occur at regular intervals and the remissions may become shorter with age Most of the patients have undergone appendectomy in childhood There is no appreciable effect on the general health or growth or development of afflicted children In more than half of the reported cases the onset took place in childhood, and the condition has been reported in the United States, Lebanon, and North Africa The cause of this syndrome is unknown Other authors have not found a relationship to allergy No infectious agent has been implicated The possibility of a neurologic background has been explored However, patients with abdominal epilepsy do not have abdominal physical signs or fever, and their attacks usually are controlled by anticonvulsant medication —G S Sturtz, M D, and E C Burke, M D, Periodic Peritonitis, *A M A Journal of Diseases of Children,* October 1956

HEALTH HAZARDS ENCOUNTERED IN REPAIR OF JET AIRCRAFT FUEL CELLS

1st Lieut. Americo R. Lombardi (MSC)
and
Capt. Arthur S. Lurie (MC), U. S. A. F.

• *In the maintenance of jet aircraft, the most hazardous physical danger results from exposure to the jet fuels while maintenance personnel are repairing or replacing the rubber lined fuel containers. The hazards involved include fire and explosion, acute intoxication from fuel vapors, systemic poisoning from tetraethyl lead, dermatitis from direct contact with petroleum hydrocarbons, and the acute psychological factor of confinement. In a study of 12 men who carry out fuel cell repair, occasional central nervous system reactions occurred among those who did not wear masks while performing their duties. The type and cause of the reactions point out the safety measures to be taken.*

The health problems encountered by Air Force personnel engaged in the maintenance of jet bombers could, in the not-too distant future, be encountered by personnel performing a similar operation on commercial jet airliners. Undoubtedly, the most hazardous of these operations is the cleaning and repair of the aircraft fuel cells, an operation potentially more hazardous than the cleaning of bulk gasoline storage tanks.

A study of this operation has been performed at Smoky Hill Air Force Base, Salina, Kan., with two principal objectives: (1) to evaluate the physical dangers that could result from chronic or acute exposure to aviation gasoline and/or jet fuels, and (2) to review the medical and engineering precautions necessary for the safety of the personnel engaged in this operation.

The fuel cells of the B-47 jet bomber are rubber-lined cubicles that fill cavities within the aircraft fusilage. Trained personnel must enter these cells to effect repairs or to remove the rubber lining entirely if necessary (*see figure*). Entrance into these cells is gained by means of small portals located on the undersurface of the fusilage and in the bomb bay. The interior of the cell provides minimal space for freedom of movement by personnel performing the operation of repair or removal. Since most of the cells are interconnected, it is often necessary to crawl from one cell into another, thus penetrating deeper into the fusilage of the aircraft and away from sources of ventilation (see figure, *B*).

It can, therefore, be readily seen that the operation is performed under extremely poor working conditions. The limited size of the access opening and the limited working space prohibit the use of cumbersome protective equipment by personnel. In addition, the very close confinement of the personnel while they are thus engaged is an acute psychological factor. Additional hazards include fire and explosion, acute intoxication from fuel vapors, systemic poisoning from tetraethyl lead, and dermatitis from direct contact with petroleum hydrocarbons.

Toxicity and Chemical Nature of Jet Engine Fuel

The figure 1,000 ppm is that most widely quoted as being the 'safe limit' for prolonged exposure, while the safe-practice manuals state that 'atmosphere within a tank which registers more than 14 to 20 per cent of the lower combustible limit is considered unsafe for breathing even for a short period of time.'[1] In the performance of fuel cell repair or removal, it has been found impractical to use these limits as a safe criterion because of the rapid build-up of toxic vapors even after ventilation for long periods of time. This is due to the interconnection of the fuel cells, which allows the fuel vapors to travel freely from one cell to another, and to the limited number and size of the access openings through which the cells can be ventilated. In addition, evidence that these limits are dangerously high has been presented along with the contention that a single figure for maximum permissible concentration of solvent vapors for a number of materials such as gasoline, jet fuel, benzine, and petroleum naphtha is not practical because of the wide variation in their chemical composition.[2]

Toxicologically, the Air Force has taken the stand that jet fuel and aviation gasoline are very similar, with the noticeable exception that jet fuels do not contain tetraethyl lead.[3] However, most jet engines can and do burn aviation gasoline occasionally, producing a potential lead exposure hazard to the men engaged in the fuel cell repair work as well as to other maintenance and repair personnel.

The jet fuel presently used by the United States Air Force exists in three grades, JP-1, JP-3, and JP-4, with JP-4 the fuel in common usage at present. The chemical composition of jet fuels has general characteristics, and all three fuels utilized by the Air Force are toxicologically similar. Basically, jet fuels consist principally of aliphatic hydrocarbons, with JP-1 containing not more than 20% of aromatic hydrocarbons by volume, while JP-3 and JP-4 contain not more than 25% of aromatic hydrocarbons by volume. In addition, JP-3 and JP-4 may contain up to 0.4% by weight of sulfur compounds other than mercaptan sulfur and as much as 0.005% of mercaptan sulfur by weight. These fuels may also contain oxidation in-

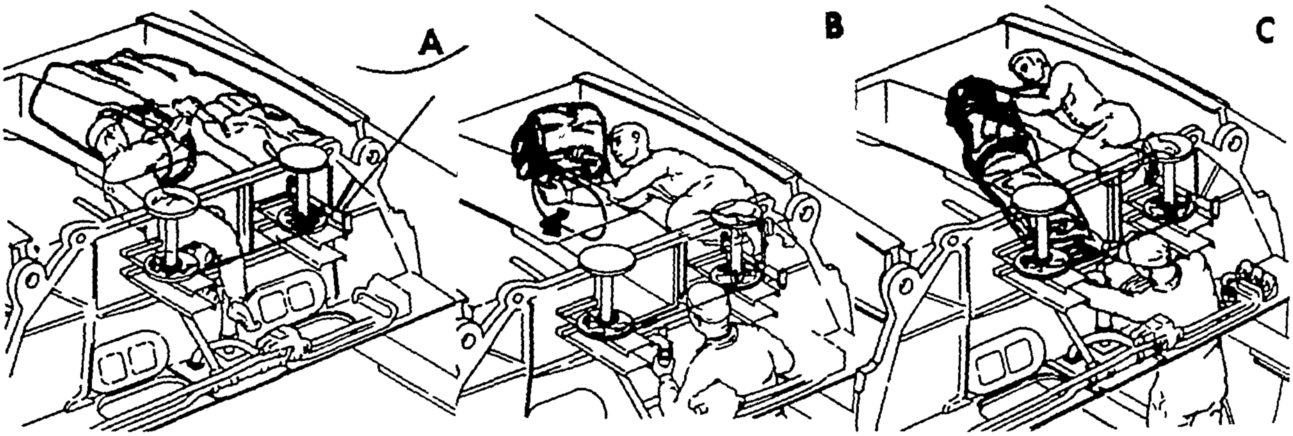
Sanitary and Industrial Hygiene Engineer (Lieutenant Lombardi) and Chief, Preventive Medicine Section (Captain Lurie), 802nd Air Division 4166th USAF Hospital, Strategic Air Command, Smoky Hill Air Force Base, Salina, Kan. Lieutenant Lombardi is now at the USAF Hospital, Schilling Air Force Base, Salina, Kan. Captain Lurie is now at the New England Center Hospital, Boston.

hibitors such as amines or phenols in small amounts

That jet fuel is toxic in the same order of magnitude as aviation gasoline is substantiated by the approximately equal percentage of aromatics present in each fuel[4] However, jet fuel is slightly less volatile due to a higher distillation temperature range, which reduces the likelihood of equally high concentrations occurring under similar conditions of temperature and pressure[5] To the man working within the fuel cells however, the resultant advantage that can be realized by this factor is almost nil

Paddy[6] states that "evidence of serious systemic injury from the prolonged inhalation of low concentrations of aviation fuel vapors is scanty and inconclusive It seems probable that concentrations low enough to produce no immediate response in susceptible persons will, upon long-repeated exposures, cause no serious chronic illness in man, but this point has yet to be established"



A position of airman in one fuel cell about to deflate lining of second fuel cell for removal *B*, position of airman in second cell cavity about to remove deflated fuel cell *C* removal of deflated fuel cell Note location and size of access portals

Dermatitis due to petroleum derivatives can be classified as contact or exogenous in nature It is most often an eczematous, follicular, or acneiform eruption Petroleum derivatives are fat solvents, which remove the natural skin oils and cause dermatitis by their defatting properties In addition, the chemicals present in fuels as inhibitors are also likely contributors to dermatitis Removal of the petroleum irritant from contact with the skin usually results in an improvement in the skin condition

Toxic Reactions

The physical examinations performed on 12 airmen (average age 23 years) who carry out fuel cell repair at this station were all within normal limits All laboratory studies also were within normal limits Because several men complained of dizziness, ataxia, and headaches during work and after leaving the cells, an attempt was made to discover if a relationship existed between the toxic symptoms and the wearing of a protective chemical cartridge mask (see table)

Occasionally there were central nervous system reactions, these occurred among those men who did not wear masks None occurred among those who did wear masks No definite evidence of chronic toxic effect was discovered in the 12 airmen examined It is highly probable that chronologically older individuals would be more susceptible to permanent organic injury

Safety Measures

Certain safety measures are recommended for personnel engaged in the cleaning and repair of jet aircraft fuel cells

1 All personnel so engaged should have preemployment physical and laboratory examinations, with follow-up examinations at six-month intervals

2 The fuel cells should be thoroughly emptied, dried, and ventilated prior to entry The use of explosion-proof blowers equipped with multiple, long-length flexible ducts for easy insertion into the multiple cells is advocated for more positive ventilation As the extreme confinement of the cell access openings makes it impossible for the men to wear positive pressure hose masks, chemical cartridge-type face masks for organic vapors have been used at this station As the efficiency of this type of mask is very limited (it is effective only at concentrations of organic vapors lower than 1,000 ppm), thorough evacuation of the fuel vapors from the cells must be accomplished before entry is made into the cells Reventilation of the cells must be carried out whenever there is a re-

Relationship Between Reported Symptoms, Wearing of Protective Mask, and Total Time of Exposure in the Cells in Twelve Airmen

Examinee	Reported Symptoms	Wore Mask	Length of Exposure Hr
1	Ataxia and occasional wobbly sensation after leaving cells	No	320
2	None	No	1 200
3	Dyspepsia indigestion	No	80
4	Dizziness (if remaining in cell too long)	No	720
5	Occasional sharp frontal headache and visual blurriness	No	400
6	None	No	480
7	None	Yes	1,300
8	None	Yes	500
9	Echoing repetition of thoughts racing of engines fuel burns	Rarely	1,300
10	Skin becomes dry and peels when clothing becomes wet with fuel	Yes	1 632
11	None (experienced dizziness when masks were unavailable)	Yes	1 040
12	None	Yes	1 020

currence of fume accumulation in order to insure an adequate oxygen supply and to prevent fume intoxication As the protection afforded by this type of mask is dubious even under these conditions, it is advocated that the positive-pressure type hose mask be adapted for use within fuel cells, thus insuring a constant supply of oxygen and positive protection against high concentrations of fuel and tetraethyl lead vapors

3 The cleaning and repair of jet fuel cells should be performed by not less than two men, with one man outside the cell serving as the observer of the man within the cell It is advisable that these two men carry on a continuous conversation (whenever possible), so that the observer may recognize an emergency and take prompt action in rescuing the repair operator

4 Clean, light-colored clothing of a material that is *not conducive to a build-up of static electricity* should be worn by personnel entering the cells This clothing should be changed and laundered upon the completion of a day's work or when it becomes contaminated with fuel

5 Lightweight rubber gloves and shoe packs should be worn by the personnel working within the cells

6 The workers should bathe at the end of each day's work or after any contamination of the body with fuel

Summary

Twelve airmen were examined in order to review and evaluate the dangers that could result from acute and chronic exposure to aviation jet fuels It was noted that occasional central nervous system reactions occurred among the men who did not wear a protective mask All physical examinations and laboratory studies were within normal limits The findings in the 12 men included in this study cannot be considered statistically significant on the basis of the evidence presented Certain safety measures should always be followed by personnel engaged in this type of work

LASTING VALUES IN MEDICAL EDUCATION

Herman G Weiskotten, M D, Skaneateles, N Y

• *There are many groups and agencies, including industry and the lay public, whose support and cooperation are essential to the continuous advancement of medical education and medical care The teaching programs of our medical schools should not remain static Important advances have been made, such as the shift of emphasis from the didactic to the experimental and practical methods of teaching, the establishment of full time faculties, and the development of clinical clerkships Criticisms that curriculums are overspecialized and that socioeconomic and environmental factors in sickness are neglected arise in large part from imperfect communication between groups, they indicate a need for the establishment of mutual understanding and cooperative relationship, especially between the schools and the local medical profession Unilateral action has sometimes proved detrimental to all concerned Continued progress depends on cooperation, especially on the part of leaders in both medical education and organized medicine*

In this, my last address as Chairman of the Council on Medical Education and Hospitals of the American Medical Association, I had anticipated expressing my great satisfaction with the present continuing development of medical education and the enormous progress that has been made in recent years I had anticipated congratulating the medical schools on this progress and on the recognition and support received, not only in this country but throughout the world

However, as I have reviewed the various criticisms that recently have been directed toward our medical schools and their educational programs, I have been forced to the conclusion that many believe that all is not as well as I had thought Some state that medical education is in a period of revolution, some, that it is in a period of transition, and others, that it is missing its objectives of training physicians for the care of patients Still others state that it is training technical specialists rather than practitioners of medicine and, further, that there is an almost total neglect of the patient as a person and of a host of socioeconomic factors that frequently play a major role in the prevention, diagnosis, and treatment of disease

Most of these indictments have come from individuals outside of the field of medical education who have special interests in socioeconomic, psychological, and public health fields as well as in the over-all problems that they consider involved in the complete medical care of the American public In the main, however, these individuals have had no experience or

---

Chairman, Council on Medical Education and Hospitals of the American Medical Association

Read before the 53rd Annual Congress on Medical Education and Licensure, Chicago, Feb 11, 1957

have no competence in the field of medical education. As a rule they have no first-hand information as to the details of the educational programs of the medical schools of the country. They look to the medical schools to solve the problems they visualize in these fields. Many of these individuals apparently are living in a world of words and phrases that they do not find listed in the curriculum outlines of the medical schools. They, therefore, conclude that nothing relating to these words and phrases is in any way touched upon in the undergraduate program.

Moreover, the activities of these groups and the support available from some of them have had an impact on many of the medical schools, inducing them to accept these indictments as justified. As an illustration of such impact, I quote a recent statement by the dean of one of our leading medical schools: "Our preoccupation with scientific medicine has tended to let the patient fade into a faceless, nebulous creature, often no more than a number on a test tube or an entry on a chart." Although I am sure that this grossly exaggerated criticism was intended to stimulate thoughtful study, it was understood by many to justify fully the previously mentioned indictments and to point out the need for revolutionizing medical education.

I do not wish to suggest in any way that the teaching programs of our medical schools should remain static. As in the past, so in the future, there will be need for changes in curriculum content and in methodology. These continually must be adjusted to changes in the scientific as well as in the clinical and social aspects of medicine. However, new material and new approaches should be adopted only after careful and intelligent study and experimentation by the faculties of our medical schools. The schools should never adopt changes merely as a result of unintelligent propaganda having its source from the outside, or as a result of pressures from the administration of the university, or even as a result of pressures from within the medical school itself.

In view of all these circumstances, I have decided to base this discussion on my personal observations and my review of the changes that have been and are now taking place in medical education. As one who has been intimately associated with medical education on a local and national basis for nearly half a century, I believe there is some justification for this effort.

The Flexner Survey

My interest in medical education began about the time of the Flexner survey. I well recall the visit of Drs. N. P. Colwell and Abraham Flexner to my school in October, 1909. At this time there had been developed laboratory exercises in the basic science courses in most of the better medical schools. However, these were, in general, "cook book" courses illustrating various demonstrable aspects of the material covered in the lectures and textbooks.

The course in anatomy was almost wholly limited to pure morphology and frequently involved the learning of rhymes to assist in the memorization of various anatomic structures. The main emphasis in the physiology laboratories was on muscle-nerve physiology. In bacteriology, most of the time was devoted to the making of culture mediums and to studying the cultural characteristics of bacteria. In pathology courses, students spent much time in staining and mounting sections that usually proved entirely unsatisfactory for microscopic study. I still remember how severely I was criticized in 1914 for the publication of a paper recommending the use of loan collections of well-prepared sections in order to provide time for using the experimental method in teaching pathology.

Teaching in the clinical years was almost entirely by lectures and by textbook assignments, with occasional medical and surgical amphitheater clinics and ward walks. Diagnosis was taught in a manner similar to that of the use of a set of football signals, with various groups of findings leading to the diagnosis of specific diseases. In practically all courses, efforts were made to cover completely a chosen textbook and, in general, emphasis was placed on the presentation of masses of often unrelated facts. Outpatient teaching largely involved practice in bandaging and in the prescribing of drugs for the symptomatic treatment of ambulatory patients.

Faculty meetings, when they were held, involved accusations and counteraccusations by preclinical and clinical teachers and involved demands by influential specialists for more and more hours for lectures and clinics. A relatively large percentage of graduates entered practice immediately after graduation from medical school.

Although a few medical schools are justified in considering the foregoing statements as an unwarranted indictment of their then-existing programs, I can assure you that these statements do represent a true picture of the general level of medical education at that time. A few schools, notably Johns Hopkins Medical School, had been developing programs based on sound educational and scientific principles. These schools, together with a group of competent and dedicated individuals serving as faculty members in other medical schools, were to serve as the "torchbearers" in the advancement of medical education.

The great impact of the Flexner report was such that medical schools were forced to give serious attention to the improvement of their educational programs. Proprietary medical schools soon disappeared, and medical education passed out of the hands of isolated groups and was turned over to the universities. There resulted an increased interest in the programs of the Association of American Medical Colleges and of the Council on Medical Education, which had assumed roles of accreditation. Attendance at the Annual Congress on Medical Education and at the meetings of the Association of American Medical Colleges increased markedly. The programs of these meetings dealt with the problems and new developments in the educational programs. Visits by representatives of the college association and the Council provided opportunity for the discussion of the programs of the individual schools.

Medical Science Developments

Advancements in the medical sciences emphasized the necessity of students receiving a thorough grounding in the basic medical sciences if they were to apply these in their clinical training and later practice

Establishment of Full time Faculty—It became apparent that the character and training of the faculty, together with its interest in contributing to the advancement of medicine and its effective influence on students, more than any other factor, determined the quality of a medical school The employment of a competent full-time faculty and the provision and support of properly equipped laboratories for teaching and research in the basic medical sciences marked the first great advance in medical education It also greatly increased the cost of operating a medical school

The justification of increased cost was made clear by the changes that occurred in the teaching programs of the basic science departments of the schools undertaking the new developments There occurred gradual and continuing changes in viewpoints, objectives, course content, and methodology Emphasis was placed on the experimental rather than the descriptive approach to the subjects Large classroom lectures and discussions tended to be replaced by small group conferences Here, students were stimulated to think and to understand, rather than merely to memorize More and more attention was given to general principles and their application in clinical medicine For example, it was found that much of physiology could be taught in terms of human physiology by using the same instruments and procedures that students would later use in the clinical departments As advances in the basic medical sciences rapidly progressed, and as the advisability of adding new material increased, thoughtful consideration was given to the relative importance of the various elements of the course content

The establishment of full-time basic science faculties unquestionably better enabled the medical schools to implement their obligation to transmit knowledge As institutions of higher education the schools were now in a position to assume more fully the additional obligation of expanding the borders of knowledge through the research activities of their staffs The change in the educational environment that was incident to the research atmosphere so created has been of untold importance in the scholarly growth of medical students

Development of Clinical Clerkships—The success of the adoption of these sound educational concepts led to a consideration of their application in the teaching programs of the clinical departments Didactic exercises and amphitheater clinics provided little opportunity for students to apply their training in the basic medical sciences to the field of clinical medicine

Perhaps this led to the greatest single advance that has ever been made in the undergraduate clinical training of practitioners of medicine, that is, the development of the clinical clerkships Students were provided an opportunity to apply their training in the basic medical sciences in the diagnosis and treatment of disease They acquired training in the proper approach to problems in clinical medicine They were stimulated to do independent thinking rather than merely to accept and try to remember statements made in textbooks, didactic exercises, and amphitheater clinics With the large amount of time required for the establishment of clerkships, the clinical faculties were faced with the problem of determining their objectives Volume of coverage gave way to completeness in the basic training of the students in the proper approach to patients and to the problems of clinical medicine The number of didactic exercises was greatly reduced, and, with proper supervision, the education and training in the clinical years became individualized

Teaching and Research Programs—The dual allegiance of part-time and volunteer clinical teachers to their private practices and teaching responsibilities served to point out the importance of providing a central core of teachers serving on an essentially full-time basis in the major clinical departments These full-time teachers were needed to provide the desired supervision of clerkships and to initiate the desired research programs Fortunately, some of the few medical schools that pioneered in the early development of these advanced educational and research programs were producing a group of well-trained clinical men interested in academic careers of teaching and research Such men frequently served as the key personnel in the development of similar programs in other medical schools Furthermore, their interest in research and in the advancement of medicine greatly broadened the programs and responsibilities of the medical schools

At the beginning of these developments only a small part of the medical research in this country was conducted in medical schools In recent years the great preponderance of scientific advances in medicine have evolved from the research programs conducted in the basic science and clinical departments of our medical schools At the same time, such advances, together with the development of diagnostic and therapeutic procedures essential to their proper application in clinical medicine, have required a better understanding of the basic medical sciences than was previously considered essential to the successful practice of medicine

In the conduct of their teaching and research programs, the schools have played an ever-increasing role in establishing the highest possible standards of medical care both in their teaching hospitals and throughout the area in which they are located

Progress in Medical Care—All of these developments have enormously increased the cost of operation of our medical schools However, these increased costs have been fully justified by the fact that in recent years the health and medical care of the public have improved more than in all previous history Such progress has been the result of the application of the advances in medical science in the training of physicians Although we must recognize that not all of our medical schools have as yet been able to effect as full a development as desirable of the educational and research advancements to which I have referred, their underlying philosophy and patterns have been recognized as sound Many schools are in urgent need of the basic facilities, personnel, and financial support for these developments

If I am correct in this brief outline of the changes that have ocurred in the programs of the medical schools and of the effect of these changes on the advancement of medicine and the medical care of the public, we must retain the lasting values that have been successful in meeting our objectives of providing for the public the highest type of medical care commensurate with the ever-increasing advancements in our understanding of medical problems

Organizational and Other Support—Time will not permit any detailed discussion of the various agencies and factors involved in the continuing development and expansion of the teaching, research, and service programs to which I have referred This continuing development has been due, in part, to the combined and cooperative efforts of the Association of American Medical Colleges and the Council on Medical Education and Hospitals of the American Medical Association, which, during the past 15 years, have worked in ever closer cooperation through the functioning of a liaison committee Some idea of the extent of the programs of these two bodies is indicated by the changes in their budgets in the past 15 years The budget of the Association of American Medical Colleges was increased from $31,500 in 1941 to $366,400 in 1956 The budget of the Council on Medical Education and Hospitals increased from $84,500 in 1941 to $410,000 in 1956

These two organizations, in addition to maintaining close relationships with the individual schools, have worked in close cooperation with the American Hospital Association, the Federation of State Boards of Medical Examiners, and a host of other groups and agencies interested in the advancement of medicine Without the cooperation of these groups, the medical schools would have found it difficult or impossible to develop their undergraduate and graduate teaching and research programs to the high level they have now attained

Throughout the entire period of these developments, much of the financial support and stimulus has been provided by philanthropic foundations and the private citizenry of the country Private industry and governmental agencies have greatly increased their support of medical education and research Never before have funds for the support of medical research been as readily available to the medical schools as they are today However, there still remains urgent need for the basic support of many of the schools The present trend away from categorical and toward unearmarked grants offers unusual promise for the sound and continued advancement of both the teaching and the research programs of the schools

Criticisms of Medical Education

I would like to expand briefly on some of the present criticisms of medical education referred to in my opening remarks

Trend Toward Specialization—To charge the medical schools and their educational programs with responsibility for recent trends toward specialization is to my mind entirely unwarranted Rapid advances in the field of medicine as well as in other fields of endeavor naturally have led to increased specialization In fact, failure to specialize would tend to deny to the public the advantages incident to many of these advances It is true that, especially in medicine and engineering, these trends have presented both educational and service problems However, whether we like it or not, specialization is here to stay In medicine we can take much satisfaction in the development and recognition of sound graduate programs for the training of specialists

Present undergraduate programs in our medical schools are in no way directed toward the training of specialists As emphasized by the Association of American Medical Colleges, medical schools properly have as their objective the provision of a solid foundation for a physician's continued development, regardless of the nature of his future career in the broad field of medicine It would be tragic if any sound educational program, basically designed to produce what might be called an 'undifferentiated physician," were altered in an attempt to resolve problems of general practice or medical practice in any particular form

I should like to add that, personally, I have no sympathy with certain efforts to induce a student, upon his admission to medical school, to commit himself to a specific type or location of medical practice

Neglect of Socioeconomic and Environmental Factors—Those who accuse the schools of the total neglect of the patient as an individual and of neglect of the socioeconomic and environmental factors related to what is frequently referred to as comprehensive medical care seem to feel that they are advocating something new in medical education They have probably forgotten that it was a medical educator who half a century ago pioneered in the field of medical social work

In my own medical school, more than 25 years ago, students serving as clinical clerks began to visit the homes of a certain number of patients assigned to them on the wards of the teaching hospital This practice is still continued The specific objective is the study of all of the various factors related to the patient's illness Experimentation with other carefully considered methods of giving the undergraduate student a proper viewpoint of the importance of these factors is to be commended, as long as such experimentation in no way lessens or weakens what I have referred to as the lasting values of a student's education and training Probably some schools have tended to neglect consideration of this aspect of medical education It is my own opinion that, where included, this aspect should be incorporated as a part and parcel of a student's clinical training rather than as a superimposed exercise or assignment

Under any circumstances we should remember that medical students are probably not as unfamiliar with these factors as some would have us believe Practically all of them have been members of families for 20 years or more before entering medical school The need for various forms of student aid suggests that they also have some familiarity with the economic problems of life Furthermore, as clinical clerks, stu dents come into more intimate and continued contact with individual patients and their problems than has occurred before in the history of medical education Finally, I resent the implication that the clinical teachers in our medical schools are a group of heartless scientists with no interest in the patient as an individual

Local Opposition to Medical School Programs

The very nature of advances in the teaching of medicine has resulted in the clinical departments playing a more active role in the medical care of the people of the area in which a medical school is located The policies of the medical schools have been varied in regard to privileges of the essentially full-time clinical faculty to conduct a limited amount of private practice Some of these policies have been seriously questioned As a result, in a few instances, certain local medical groups have handicapped or opposed the full development of the clinical departments of schools These groups sometimes fail to realize that the work of the men on the clinical faculty is essential to the sound progress of medical education and that an attitude of opposition rather than fair and just integration is a real threat to the very structure of modern medical education Local private practitioners not only should have an interest in medical education but should have much to contribute to it The establishment of clear understanding and cooperative relationships between the schools and the local medical profession should work out to the best interests of both groups

Comment

May I emphasize that our present programs of medical education are by no means perfect and probably never will be Nor do I believe that uniformity of the details of the curriculum of our medical schools is in any way desirable I have tried to refer briefly to the advances in the undergraduate programs of the medical schools that I consider to be of such lasting value that they should be carefully guarded less they be diluted or lost And I believe there is danger of losing them if organized medicine, university administrators, or even medical school administrators yield to popular pressures and attempt to dictate the policies or the educational programs of our medical schools

Undergraduate medical education must be left in the hands of medical educators, that is, in the hands of the experienced members of the faculties of the medical schools Only they are in a position to evaluate and deal with the complex problems of laying a foundation for a student's future career as a physician The time presently allotted to the undergraduate course is already extremely short, especially in view of the rapid advances in certain of the fundamental aspects of medical diagnosis and medical care Under no circumstances can we hope to give the undergraduate student the maturity, judgment, and attitudes in regard to all of the so-called practicalities of medicine that can only be acquired by his subsequent experiences in his hospital training and practice

Recognizing that the stated objectives of both medical education and the organized medical profession are the advancement of medicine and the provision of the highest type of medical care possible, I would like to make a plea for medical educators to take a more active part in the activities of organized medicine Organized medicine needs the assistance and advice of the medical educators of the country in dealing with many of the problems with which it is faced

Furthermore, I would like to make a plea for organized medicine, through its Council on Medical Education and Hospitals, to confer with the Association of American Medical Colleges in regard to problems relating to medical education Without such cooperation, even in the face of the best intentions, there may result in the future, as in the past, unilateral actions that may be detrimental to organized medicine, medical education, and the medical care of the public

There is a host of other groups and agencies, including industry and the lay public, whose support and cooperation are essential to the continuous advancement of medical education and medical care Surely, if leaders in these important areas of human endeavor approach their joint problems with the sole purpose of seeking resolutions that will best serve the interests of the public, much of the present controversy will disappear

In closing, may I express the hope that, after this glance over the road that medical education has traveled, you will agree with me that the progress made is indeed worthy of a commendation So much distance, including the steep hills with many obstacles, has been traversed as to make it clearly evident that our faculties have consistently recognized and chosen the way of lasting values I have every confidence that they will continue in this advance, pausing only on occasion, to read and intelligently interpret the signs indicating side roads of transient worth

5842 Alton Rd , Miami Beach, Fla

Hemosiderosis and Blood Transfusions—Periodic blood transfusions may be life-sustaining for patients with a refractory, chronic hemolytic, or aplastic anemia, but the necessity of such regular administration of blood is liable in time to result in hemosiderosis Since every pint of blood carries into the patient's body approximately 250 mg of iron and since there is no pathway for excretion of iron, the giving of large numbers of blood transfusions gradually leads to the deposition in various organs of the body of considerable quantities of iron which may in time interfere with their functions Hemosiderosis may affect the bone marrow, myocardium, kidneys and adrenal glands The liver may become cirrhotic or diabetes may result from siderosis of the pancreas—H F Brewer, M D , B Ch , The Hazards of Blood Transfusion, *The Postgraduate Medical Journal,* June, 1956

ORIENTING MEDICAL STUDENTS TOWARD "THE WHOLE PATIENT"

John C Whitehorn, M D , Baltimore

• *In orienting the student to the patient, a major task is to mobilize the common sense insights that the student has already developed and to help him in organizing them and in examining their relevance to professional operations in the field of health and disease Visiting the patient in his home is not always better than seeing him in office or hospital settings, unless the student is prepared to overcome the social habits of polite evasion and tactful prevarication and to discuss essential matters with genuine respect, tact, and thoroughness After such orientation, his course is determined by two general types of factors One is the practice, counsel, and good example of admired young leaders, the other is the influence of a continued, liberal, humanizing education The student who is encouraged to use all university resources, liberal as well as technical, is likely to gain a good conception of the physician's responsibility that is implied in the phrase "the whole patient "*

In the strenuous reappraisal of medical education that has been proceeding so vigorously in the last two decades in America, the words "integrative" and "comprehensive" appear with great frequency These adjectives give expression to efforts at improvement, and they imply some dissatisfaction with medical education and medical practice The dissatisfaction is pointedly focused upon an educational process that has appeared too fragmented and upon a pattern of medical practice that is stigmatized as too specialistic or too technological At the same time it is vigorously asserted, and generally acknowledged, that health service in this country is at a higher level of excellence than ever before Indeed, it seems probable that the enthusiasm over its excellence provides a powerful motivation for proceeding vigorously toward the remedy of the defects in medical education

The recognition of defects has been stimulated, in some measure, by public criticism It is not that the public is antagonistic toward doctors Public attitude surveys show that medicine enjoys a very high prestige But there are criticisms Two common criticisms are that individual physicians do not show appropriate human understanding and that the medical profession in general shows little understanding of social processes affecting health If these criticisms are creditable, they appear to point up some defect in the preparation of persons in the medical profession There could, theoretically, be an alternative explanation, that persons entering the profession of medicine have little interest in human beings and human problems Admissions committees are much concerned about the selection of medical students and about the premedical phase of education There are academic processes that distort this selection and that disorient students to human and social values

In 1951, in a conference on psychiatry and medical education, sponsored by the American Psychiatric Association, there was submitted a rather extensive review of opinions obtained from a selected list of knowledgeable laymen A brief quotation from one citizen may serve to epitomize the comments of many He wrote

> Many doctors treat their clients as mere patients, rather than as fellow human beings Many doctors whom I know are congenial fellows, but in their relationships with the patients they ve the impression of being hurried There is a certain assembly ne attitude and aloofness to which the patients are keenly itive It is no wonder that quacks by the thousands thrive because they listen, they sympathize and they give the impression of sincerely desiring to help, even though they do not have the proper medical training if any at all

Critics within the medical profession have been somewhat harsher, pointing up not merely an irritating lack of graciousness and human sympathy but instances of doctors' serious misunderstandings and failures in professional obligations because of the failure to recognize emotional factors in the patient s distress or disability These critical remarks need not be multiplied What I have said will suffice to focus attention upon the need, in medical education, for orienting doctors more effectively toward the patient as a person My discussion shall be concerned most directly with the consideration of how this need may be met

Role of Psychiatry

There is a common belief that what needs to be learned can be taught The assertion has been made that doctors do not understand human nature or do not use this understanding in their professional work, hence, somebody should teach them this understanding and how to use it in their work The task of leadership in such teaching has been assigned to the department of psychiatry in the typical American medical school of today Why?

First of all, in explanation, it should be said that psychiatrists have been granted such opportunities and responsibilities because they sought them They felt that they had, in recent decades, developed within psychiatry a considerable body of useful knowledge, theory, and skills regarding personality and the ways of dealing with emotional processes This body of knowledge seemed to offer to physicians in general a useful basis for understanding and dealing with human nature

The core of this modern psychiatric insight and working methodology lay in a very simple and elementary proposition, namely, that those oddities of behavior, thought, and feeling that constitute the

---

Director, Department of Psychiatry, and Henry Phipps Professor of Psychiatry, Johns Hopkins University School of Medicine

Read before the 53rd Annual Congress on Medical Education and Licensure, Chicago, Feb 11, 1957

symptomatology of the psychotic and neurotic types of illness are found to have human meaning with relevance for him in motivation That is, these oddities are found to be relevant to the issues and conflicts of life This proposition is usable (and this is the key clause) if one can gain a sufficiently penetrating understanding of the personality and the situation Psychiatric symptoms have personal meanings, and patients can be helped in their conflicts and in their life situations through the physician's understanding of these meanings It can be said also that many medical situations involve similar personal meanings and emotional implications, often useful and important in a treatment program

It is easy to assume the fallacy that when one has penetrated to the meaning one has penetrated to the cause This vulgar fallacy of identifying meaning and cause has confused the psychiatric literature and has created difficulties in presenting to medical students the basic insights into human nature that have been reliably gained by psychiatrists This fallacy is commonly compounded with the fallacy that anything that is psychological can, of course, readily be changed Actually some patterns of expectation and action, developed through significant life experience and repetition, become deeply imprinted and practically unalterable There is no sure way, other than empirical study and trial to know which kinds of experientially developed patterns are unmodifiable and which are modifiable, and how

Knowledge of Human Nature

These brief comments may serve to indicate, in a general way, some of the special difficulties in selecting appropriately the useful and reliable parts of that dynamic knowledge of human nature gained by psychiatrists in their special field Then comes the task of bringing such knowledge and possible skills to the student's attention and engaging his interest

The major task, however, in orienting a student to the patient as a person is not instructional in the sense of selecting and presenting information The major task is to mobilize the common-sense insights that the student has already developed, or almost developed, and to help him in scrutinizing and in organizing his own insights and in examining the relevance of these insights for professional operations in the field of health and disease To stimulate the mobilization of such common-sense insights in the student, it is useful to set him to work studying examples of human adjustments to illness, particularly examples of good adjustment He should also seek an understanding of the personality resources that potentiate good adjustment, and of the influences of family and social background favorable to the development of good adjustment potentials In many ways such an effort to bring to expression the student's own increasing organization of himself in the service of his professional work is analogous to the functions of a liberal education, and probably, in essence, it is identical

It has appeared to me that the most useful of the general guidelines in the instructional part of this type of program have been those provided by what we know and can sensibly formulate about personality development Some of the basic ideas can be succinctly stated here

Human beings, as we know them, are inescapably interdependent They live with and for one another Man is not well equipped, biologically, for completely independent living, but he has been provided with emotional potentialities for a life of domestication and socialization Through the educative experiences thus made possible, individual persons develop their personalities, and thereby their interests, make their basic commitments to values, and acquire, in the process, certain conflicts of interests They achieve also some measure of maturity for dealing with their responsibilities and opportunities It is a zig-zag progress, not clearly straightforward One begins weak and helpless and must, perforce, learn first the domesticated ways of gaining affection and favoritism as a baby Later, as a child, one develops strength and skills and, in the security of the family's way of life, explores the available range of self-assertive and adventurous behavior, and then later, sometimes much later, one develops responsiveness to others' needs and fills the roles of responsible domesticator and provider

In the college dictionary, the student can find man characterized as Homo sapiens, and it is good for one to recognize man's sapience In a wise-cracking mood one may abbreviate it to Homo sap, and surely the doctor needs to understand human folly But the medical student's dictionary should characterize man primarily as Homo domesticus, a domesticated creature, living in a family and developing, in the family setting, the basic emotional attitudes and conflicts of interests that may later enthuse or bedevil his interdependent existence These attitudes and conflicts he is likely to carry with him on the job, in the hospital bed, or in the doctor's office The wise doctor does well to envisage each patient in a domestic frame of reference

In a number of the current experiments in medical education, the effort is made to get the medical student to cultivate this domestic frame of reference for understanding human nature by assigning him to a family or inviting him into the family situation This seems like a realistic method of education, yet it may fail People have been living in homes and passing through the homes of others for a long time, but they may remain extremely obtuse as to the emotional situations existing there Indeed, for most well-brought-up people, proper manners require a certain degree of obtuseness, just as proper manners in ordinary life require a politely optimistic prevarication in reply to the social greeting "How are you?' There are additional conventions, or cue systems, especially suited to the well-defined roles of doctor and patient, which, for example, permit the patient, but not the doctor, to express how miserable he is Sometimes these cues get mixed An addled patient may reply to the doctor's question by denying symptoms, or he may bring forth other polite prevarications, out of inappropriate social habit Often, the anxious medical student, without the steadying earnestness of clearly defined and familar tasks, visits a family and, through lack of a clear role, gets his cue systems mixed Conversational difficulties may be produced, but also, more frustratingly, matters of emotional significance may not be comprehended, or even observed

It has been noted that a student, working as a clinical clerk on a ward service, may through interviews with a patient in that setting, gain a comprehension of a patient's domestic anxieties and tensions that is much more penetrating and usable than that gained by visiting in a patient's own home Indeed, patients themselves sometimes get a better understanding of their own home situation by getting out of the home and going to a doctor's office for a talk with the doctor The meaningfulness of domestic situations inheres more directly in the persons than in the house or the furniture Words truly have their limitations, but the opening of the mouth in speech in a suitably cued situation may yield a more useful understanding of a domestic life situation than can be gained by opening the actual door to the living room, or even the bedroom, and examining the establishment

The cue systems of the sociability settings in which medical students have learned their manners have provided some conventional prevaricating patterns of tact and of evasive politeness When one is undertaking the role of physician, however, it is expected that one will have the courage and understanding to discuss many matters not accessible under the sociability cue system, and to discuss them with genuine respect, a special kind of tact, and with thoroughness

Consider, for example, that the usual polite conventions of conversation or public talk discourage or prohibit the mention or the discussion of the less noble motivations, or the less highly regarded features of personality, such as immaturity, yet how necessary it is to have some comprehensive grasp of these subjects, beyond the superficially polite level, in order to have a professionally useful understanding of the problems of human interaction needed in comprehensive patient care Students need the guidance of sound and penetrating theory in the deeper understanding appropriate to professional work They also need emotional support in the early phases of gaining practice and skill in interacting with patients at the more fundamental level

The medical student, in the clinic or hospital setting, may well feel more poised and secure than on a home visit He wears a white coat and has his stethoscope at hand, not for stilted show but because he uses it regularly He has a definite and dignified function and can bring himself more fully into the interview, with a greater likelihood of having a clear head and of being alert to possible emotional issues than when he is in the patient's home, vaguely imitating a social worker or a somewhat indefinable benevolent visitor

For these reasons and others, it appears to be doubtful that the mere physical entrance into homes brings a very constructive gain for that early phase of medical education designed to provide a basic orientation to human nature At an appropriate later stage, when he has developed a more secure professional orientation, the young doctor will find in home visits good opportunities for broadening his range of understanding and supplementing his acquaintance with the great diversity of domestic cultures

Determinants of Integration of Knowledge

Assume that the student has been aided in developing some framework of thought about personality and personality development for orientation to patients as persons, somewhat along the lines already suggested, incorporating as much as possible of his own share of common sense, and that he has received some primary guidance in interviewing patients One then comes to the crucial conditions that determine whether all this will become an inherent part of the student's working methods or be forgotten and neglected along with much else called basic science The crucial determinants are of two general types on the one hand, practice and counseling therein and, on the other hand, some continuation of liberal and humanizing education

Let us consider first the practice and counseling One might assume, since all patients are in fact persons, that this simple fact and its major emotional implications would be constantly clear to any student working with patients and that this obvious truism would guide the student aright I have heard that S Weir Mitchell, the famous neurologist, when asked to discuss the doctor-patient relationship, remarked testily that all physicians were gentlemen and would therefore know how to manage any personal relationships properly and, if they were not gentlemen, there was nothing that could be done about it But it is our experience that students, when reasonably well oriented to the possible medical significance of emotional reactions, do encounter problems and do seek guidance about the emotional problems of their patients, whenever competent counselors are readily available in their working situation In our program at the Johns Hopkins Hospital we have tried to make such persons available, particularly during the strategic clinical clerkships in internal medicine and pediatrics Without such guidance and support in evaluating and dealing with emotional factors, the primary orientation would probably be futile or mischievous in effect

In this connection it should be emphasized that the resident staff in a teaching hospital have a preponderant influence on the student attitudes regarding all the basic sciences We used to lament the great gap, almost an attitude of opposition, between the preclinical and the clinical parts of medical education, but the causes for lamentation have considerably decreased with the increasing activities of residents and fellows in the fields of basic sciences in close relation to clinical problems The contagiousness of such interest and respect, as it affects the medical students, has constituted one of the principal integrative forces in medical education The same general principle holds also in regard to the kind of study given to the patients as persons The earnestness and effectiveness of such study is like the phenomenon of induction The student directs his efforts along lines where admired young colleagues lead

I have mentioned as a second crucial determinant of the effectiveness of this aspect of medical education the continuation of liberal and humanizing education It is trite to say that education is a never-ending effort for anyone in the medical profession It is also trite to say that, in large part, this continuing education must be self education In some medical schools this is not merely a trite remark but a principle of action, and an appreciable portion of student time is reserved for individually directed education, or at least opportunity is maintained for individually selected studies The earnest pursuit of knowledge and insight into human problems is the natural accompaniment of any vital interest in patients as persons Individual students and individual doctors do at times find time and method for self directed enlargement of their liberal education, along humanistic, social, and historical lines I hope, however, that, in the future, universities will offer more opportunity and encouragement to medical students to use all university resources, liberal as well as technical, for their fuller education, that the medical part of the university may be less a technologically segregated unit, and that, as the need becomes individually apparent, the students may have further opportunities to overcome unexpected inadequacies of earlier phases of education These measures would assure that the conception of the physician's responsibility that is implied in the phrase "the whole patient" would be granted a greater chance of viability in "tomorrow's medical education"

601 N Broadway (5)

SCIENCE AND MEDICAL EDUCATION

Dana W Atchley, M D , New York

• *Three essential qualities of the ideal physician are that he be a cultivated man, that he be capable of compassionate and perceptive responses, and that, above all, he be a scientist, for it is this quality that distinguishes him from any of the well veneered and sympathetic practitioners of the healing arts The primary responsibility of the medical school is the development of scientific understanding, and the curriculum must be oriented more to understanding than to knowledge*

There is always a certain amount of embarrassment attached to the offering of ideals, particularly if they approach the unattainable Yet unattainable ideals are valuable when they serve as goals that stimulate and guide progress, they are a handicap only when failure to reach them discourages further endeavor I shall therefore venture to mention briefly three essential qualities of an ideal physician We should require of this not-too-hypothetical individual that he be a cultivated man, that he be capable of compassionate and perceptive responses, and, above all, that he be a scientist, for it is this quality that distinguishes him from any well-veneered and sympathetic practitioner of the healing arts

The exaggerated respect evoked by the healer affords him a remarkable influence, not only on his patients but on his total social area If he be a person with appreciation of cultural values, familiar with history, liberal in thought, devoted to the finer things, he can exercise an elevating influence of great value in most environments These assets of a cultivated man are derived essentially from his family and from his education prior to medical school Our opportunity to further this component of the good physician lies mainly in recognition, by admissions committees, of the candidates who manifest it I agree with the minority opinion that cultural "bird's-eye" courses are a poor pedagogic approach to this problem in the college years I prefer a man who has dug deeply into one of the humanities to one who has scratched the surface of many fields, a cultivated man is more a scholar than a dilettante

Sympathy, compassion, and a quick, warm responsiveness are basic attributes of the healer and have been a major source of his success from first recorded medical history, their value is in no way decreased by the other services the present-day physician has to offer What was almost the sole contribution of the physician in the previous century is still his main gift in many cases A self-identifying awareness of the feelings of others is largely an inborn trait, but the influence of a kindly home and exposure to such attitudes in medical school can awaken and amplify this facet of the ideal physician It is difficult to recognize these qualities with any degree of accuracy during an admissions interview, and, moreover, their absence would not handicap a man headed for an investigative career

While it is highly desirable for our ideal physician to have culture and compassion, it is imperative that he be a scientist, and therefore the primary responsibility of a medical school is the development of scientific understanding If the student arrives with a good background the task is easier, but, at best, it is a colossal task and the time available grows less and less adequate

Role of Science in Medicine

It seems strange that in mid-20th century one should be constrained to enter a defense of the role of science in medicine Yet presently there are strong movements aiming to dilute the medical curriculum with time spent on attempts to inculcate social respon-

Professor of Clinical Medicine, Columbia University College of Physicians and Surgeons

Read before the 53rd Annual Congress on Medical Education and Licensure Chicago, Feb 11, 1957 miliar tasks, visits a family and, through lack of a clear role, gets his cue systems mixed Conversational difficulties may be produced, but also, more frustratingly, matters of emotional significance may not be comprehended, or even observed

It has been noted that a student, working as a clinical clerk on a ward service, may, through interviews with a patient in that setting, gain a comprehension of a patient's domestic anxieties and tensions that is much more penetrating and usable than that gained by visiting in a patient's own home Indeed, patients themselves sometimes get a better understanding of their own home situation by getting out of the home and going to a doctor's office for a talk with the doctor The meaningfulness of domestic situations inheres more directly in the persons than in the house or the furniture Words truly have their limitations, but the opening of the mouth in speech in a suitably cued situation may yield a more useful understanding of a domestic life situation than can be gained by opening the actual door to the living room, or even the bedroom, and examining the establishment

The cue systems of the sociability settings in which medical students have learned their manners have provided some conventional prevaricating patterns of tact and of evasive politeness When one is undertaking the role of physician, however, it is expected that one will have the courage and understanding to discuss many matters not accessible under the sociability cue system, and to discuss them with genuine respect, a special kind of tact, and with thoroughness

Consider, for example, that the usual polite conventions of conversation or public talk discourage or prohibit the mention or the discussion of the less noble motivations, or the less highly regarded features of personality, such as immaturity, yet how necessary it is to have some comprehensive grasp of these subjects, beyond the superficially polite level, in order to have a professionally useful understanding of the problems of human interaction needed in comprehensive patient care Students need the guidance of sound and penetrating theory in the deeper understanding appropriate to professional work They also need emotional support in the early phases of gaining practice and skill in interacting with patients at the more fundamental level

The medical student, in the clinic or hospital setting, may well feel more poised and secure than on a home visit He wears a white coat and has his stethoscope at hand, not for stilted show but because he uses it regularly He has a definite and dignified function and can bring himself more fully into the interview, with a greater likelihood of having a clear head and of being alert to possible emotional issues than when he is in the patient's home, vaguely imitating a social worker or a somewhat indefinable benevolent visitor

For these reasons and others, it appears to be doubtful that the mere physical entrance into homes brings a very constructive gain for that early phase of medical education designed to provide a basic orientation to human nature At an appropriate later stage, when he has developed a more secure professional orientation, the young doctor will find in home visits good opportunities for broadening his range of understanding and supplementing his acquaintance with the great diversity of domestic cultures

Determinants of Integration of Knowledge

Assume that the student has been aided in developing some framework of thought about personality and personality development for orientation to patients as persons, somewhat along the lines already suggested, incorporating as much as possible of his own share of common sense, and that he has received some primary guidance in interviewing patients One then comes to the crucial conditions that determine whether all this will become an inherent part of the student's working methods or be forgotten and neglected along with much else called basic science The crucial determinants are of two general types on the one hand, practice and counseling therein and, *on the other hand, some continuation of liberal and* humanizing education

Let us consider first the practice and counseling One might assume, since all patients are in fact persons, that this simple fact and its major emotional implications would be constantly clear to any student working with patients and that this obvious truism would guide the student aright I have heard that S Weir Mitchell, the famous neurologist, when asked to discuss the doctor-patient relationship, remarked testily that all physicians were gentlemen and would therefore know how to manage any personal relationships properly and, if they were not gentlemen, there was nothing that could be done about it But it is our experience that students, when reasonably well oriented to the possible medical significance of emotional reactions, do encounter problems and do seek guidance about the emotional problems of their patients, whenever competent counselors are readily available in their working situation In our program at the Johns Hopkins Hospital, we have tried to make such persons available, particularly during the strategic clinical clerkships in internal medicine and pediatrics Without such guidance and support in evaluating and dealing with emotional factors, the primary orientation would probably be futile or mischievous in effect

In this connection it should be emphasized that the resident staff in a teaching hospital have a preponderant influence on the student attitudes regarding all the basic sciences We used to lament the great gap, almost an attitude of opposition, between the preclinical and the clinical parts of medical education, but the causes for lamentation have considerably decreased with the increasing activities of residents and fellows in the fields of basic sciences in close relation to clinical problems The contagiousness of such interest and respect, as it affects the medical students, has constituted one of the principal integrative forces in medical education The same general principle holds also in regard to the kind of study given to the patients as persons The earnestness and effectiveness of such study is like the phenomenon of induction The student directs his efforts along lines where admired young colleagues lead knowledge and are eager to learn, so patients rarely suffer from a dictatorial error by the chief, and the staff matures through interchange of divergent opinions.

With the remarkably precise organic appraisal that scientific methods make available, we are now able to evaluate, with a new degree of accuracy, the participation of other components, such as heredity, personality, and environment. Indeed, the comprehensiveness of so called comprehensive medicine depends more on scientific comprehension than on humanistic inclusiveness. The good family physician of 50 years ago was acutely aware of the important role that family, personality vagaries, economics, and ambition played in his patient's health but the physical machine was largely a mystery and psychology was wholly intuitive. Today's physician, if he will take the time and trouble to do so, comprehends the total individual to an extraordinary degree and can thank science for this improved vantage ground.

There has been a rather widespread impression, fostered at times honestly, but sometimes maliciously, that a scientific training dries up the milk of human kindness. It is difficult to trace the sources of this palpably absurd belief, perhaps it came from reading about "thinking machines" in science fiction, or perhaps from the unconscious jealousy of men not fortunate in possessing such a training. I have observed many scientifically trained clinicians and also men less lucky in that respect and I have never seen a sympathetic person frozen by a research career or a cold, tactless individual thawed by general practice.

Education of Medical Scientists

The application of the foregoing discussion to medical education is obvious. In order to ensure the highest quality of medical practice, our first and foremost duty is to graduate medical scientists. This means a curriculum oriented more to understanding than to knowledge, a student body more eager to learn than to be taught, and a faculty with sufficient investigative experience to develop a sound, critical capacity in its students. In addition, well-guided student research can be a tremendous asset in cultivating an appreciation of the philosophy of science.

A program of scientific indoctrination in medical school is greatly aided by a college training that includes courses in mathematics, chemistry, and physics and that, in at least one of these subjects, is advanced enough to give the student considerably more than a superficial understanding of the discipline involved. Furthermore, there is great value in studying one of the humanities in depth. Concentration on Elizabethan literature, anthropology, or the history of philosophy tends to produce a scholar, and the methods of thought of a scholar in any field are much the same as those of a scholar in science.

It is universally agreed among experienced educators that disciplined intellectual power is more valuable than knowledge, that the forming of the mind has priority over the imparting of information. This point of view in no way derogates knowledge per se, but it must be accurate knowledge subjected to careful scientific scrutiny. The successful teacher finds no mutual exclusiveness between the development of intellectual critique and the communication of facts. But facts in a dynamic discipline, such as medicine, are too often dated. Consequently, as the physician leaves medical school further and further behind, he must rely upon himself to appraise the soundness of new information. The scientific critique developed in medical school will be his chief guide in differentiating the true from the false. It is trite but essential in these days of anti-intellectualism to state again that the continued professional growth of the physician depends on the way he has learned to use his mind rather than on what he was able to store in it during medical school.

It is through the processes of science that meaning is attached to otherwise lifeless data. Science transforms the static into the dynamic, makes mechanism more important than morphology, and adds the delightful intellectual savor of understanding. The joy of understanding is both the closest rival of the joy of service and its most effective partner.

The continued flowering of medical science depends on the early recruiting of young investigators. Any tendency to transfer primary pedagogic emphasis from the firm hard-thinking of the natural scientist to the expedient artisanship of the practitioner will tend to discourage the creative mind. This emphasis on science in no way inhibits recognition of the value of compassionate responses. The very nature of social and economic problems calls for exceptional objectivity and austere critique, which are learned best within the university walls.

If the thesis be accepted that a medical student should in the course of his training become a scientist, we must face the very difficult problem of implementing this decision. Probably there is no more fundamental requirement for the attainment of this goal than an atmosphere of research. In every department the student should find evidence of intellectual curiosity, of man's insatiable mind at work, but in addition be should be told the exciting story of the development of knowledge so that he may experience, at least vicariously, the pains and pleasures of exploring the unknown. He should be taught to recognize the type of thinking and the quality of experimentation that has been successful in revealing new facts and relationships. The student should come to realize that, some centuries ago, a curious and thoughtful mind needed less knowledge than courage, but now courage is not so important as familiarity with a basic scientific discipline.

Although it may not be practical to offer a course in logic, there is no profession that needs it more. The undergraduate level of medical school presents the best opportunity to inculcate this invaluable gift. No matter what the subject, it is possible to point out the dangers of careless hypotheses, to contrast *post hoc* with *propter hoc*, and to present the criteria by which scientific evidence is accepted or discarded. There must be appreciation of the dangers of focusing on one variable and the omitting of controls. I have always felt that the clinician has an excellent opportunity when he teaches history-taking to insist that the data be accumulated according to the rules of logic and expressed with some attention to the precise use of language As the journalistic tendency of the clinical clerk is moulded into something approaching a scientific analysis of the patient's history, conscious emphasis on the rules of logic makes a more lasting impression than would a course devoted solely to that field

The role of science in improving management of the most practical problems can be used to illustrate to the student the importance of an understanding of the basic scientific knowledge that at times seems irrelevant to him The contributions of work on electrolyte physiology to postoperative care, of respiratory physiology to anesthesia, or of renal physiology to urology are examples of material that would orient the alert student in proper fashion

However, no manipulation of the curriculum and no brilliance of pedagogy can compare with participation in research for the production of a scientific critique Unfortunately, there is often no time or laboratory space available, and many students have neither the interest nor the capacity for investigation Nothing is more futile than forced or contrived involvement in a research problem But the schedule should be sufficiently flexible for the provision of free time to those who do have the interest and capacity, and the faculty should make a conscious effort to indicate the high value of research in the development of a modern physician Whether the student becomes a psychiatrist, a family physician, or a specialist in a limited area, he will be capable of richer service to his patients if he has, in person, experienced the discouraging but illuminating difficulties that afflict the individual who attempts to widen the perimeter of our knowledge

Conclusions

As we seek to produce the ideal physician, we can try to select cultivated men and women and we can stimulate a humanistic response by precept and example But we can create a scientist capable of coping with his evolving discipline only by establishing an atmosphere of sound critical thinking in an environment dedicated to advancing the science that is a physician's unique contribution to man's health and happiness

THE PROS AND CONS OF INTEGRATION AND CORRELATION

Oliver Cope, M D , Boston

• *Three needs of present day medical education are especially considered the need of assimilating recently accumulated knowledge, the need of recognizing the emergence of a well founded psychiatry, and the continuing need of eliminating obsolete modes of therapy Teaching methods and administrative schemes work only if vigorous teachers are available Excessive departmentalization causes a loss of educational perspective Condensation, integration, and the joining of related departments into a division should help to keep the demands on the student within reason, it should assure psychiatry its proper place in the educational plan and help to rid therapeutics of an accumulation of obsolete methods*

Much has been said and written in the last few years regarding the need for integration and correlation in the teaching of medicine If the strict definition of these words is employed, there is nothing new about their use in medical teaching Before examining the pros and cons of reintroducing them or of redeploying them in the present curriculum, let us examine past experience in their use

One hundred fifty years ago medical education was integrated It is true that the teaching of medicine and surgery were separate Medicine was taught by the professor of physick, and surgery by the professor of anatomy and surgery, but the teaching of each subject centered around the patient, and the aspects of the patient's problem were integrated into a whole So little was known, there was no other way Medical knowledge had not as yet been splintered off into separate pieces It was only as knowledge developed that the various aspects acquired a body of knowledge sufficient to be split off and studied as a separate part Here an integration of a type was employed As bits of chemical knowledge and understanding appeared these bits were assembled and integrated into the science of biochemistry Knowledge of function was later similarly assembled and integrated into the science of physiology Ideas regarding one organ were correlated with those of another, and laws of function and chemical reaction were formulated Koch's postulates were an example of such correlation

Knowledge was rudimentary when each aspect was set apart for separate study Anatomy, pathology, chemistry, physiology, and pharmacology were in their infancy Medicine and surgery were no further advanced Bacteriology dawned as a new science Pursued as separate entities, these various fields of medicine have undergone prodigious growth of understanding in the past 100 years Each field of medical science has been assigned the autonomy of departmental structure, and each department has been jealously guarded by its proprietors As far as medical education is concerned, the integration and correlation of knowledge has awaited the clinical years of medical

Read before the 53rd Annual Congress on Medical Education and Licensure, Chicago, Feb 11, 1957

school Here the clinician also preoccupied with his special interests, has often faltered and fumbled The past 50 years have witnessed many delays in the appreciation of the significance of knowledge in one field to that of another The long delay from the discovery of the sulfonamides to their clinical use is but one example Better integration and correlation could have hastened the utilization of discoveries in the care of the patient But would the integration have slowed the development of each science?

Factors Calling for Revision of Approach

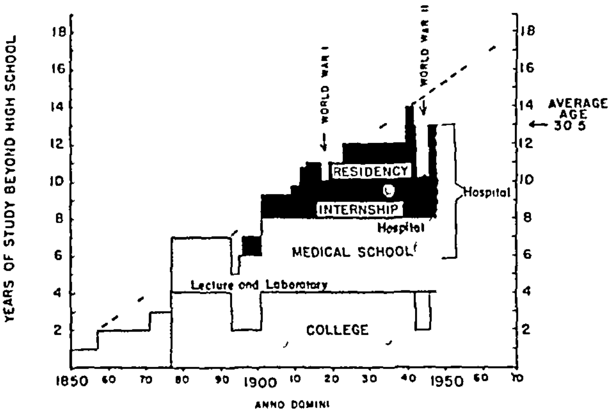
Today three separate factors cry for revision of our present approach to medical education the huge body of knowledge useful to medicine, the birth of a well founded psychiatry, and a threatening hoard of obsolete modes of therapy What is the nature of these and how far will integration and correlation answer the need for revision?

Large Body of Knowledge—What the growth of knowledge useful to medicine has done to medical education is most readily grasped by looking at the course of medical education over the past 100 years In 1850 the formal education of the would-be surgeon at the Harvard Medical School and the Massachusetts General Hospital was one year (see figure) With each decade courses have been added and the curriculum has been lengthened In 1941 his education involved a period of 14 years from high school graduation to the completion of his residency training When the additions are plotted against the year each was introduced, the lengthening of the curriculum assumes a straight line in terms of time If this line is projected to 1970 the curriculum reaches the astounding length of 18 years The curriculums of the general practitioner, the internist, and other specialists have been similarly lengthened

What has caused this lengthening of the curriculum? As each area of information important to medicine and surgery has been unfolded, and as each new fact and each new technique has been disclosed, all have been dumped into the curriculum, and the necessary months and years have been added to teach them From time to time systemization of knowledge has reduced the number of isolated facts to be learned, but, on the whole, once something has been added, little has ever been pruned Certainly no concerted effort has been made recently to discriminate between facts essential to medical education and those less likely to stand the test of time Those facts less illustrative and therefore less significant to the educational process have not been weeded out The result is that medical education is now bogged down in a welter of facts, and it threatens to become worse in the near future Medical knowledge is continuing to grow, and the curriculum will continue to lengthen unless some mechanism is found to halt it Selection of what is taught is an obvious answer, at least to this aspect of the problem Has a new application of integration anything to offer? Should the presently highly integrated medical sciences and clinical specialties be broken up (disintegrated, one could call it) and a new structure be composed of parts of each?

At this point, the following question is pertinent Is it essential that the medical student learn every fact of medical science and clinical medicine? He will not know all later on when he is a practitioner For example, should every medical student know all the details of the curare group of drugs, every last feature of the electrocardiogram, and the technical details of the management of every fracture of every bone in the body? Would it not suffice if the student learned where curare fits into the scheme of drug action and how it affects the transmission of the nervous impulse, what the electrocardiogram is, with one or, at most, two examples of its use, and the management of one or two fractures as illustrations of the principles of clinical care and bone healing?

Any effort to eliminate areas of knowledge from the medical curriculum meets with stubborn resistance In general, each faculty member thinks his own particular knowledge is of the utmost importance It is, of course, to him, since he uses it in his daily work and his achievement depends upon it It is hard for him to see that some of it may not be quite so important to others



History of the education program in general surgery at Massachusetts General Hospital from 1850 to 1950 From a length of one year in 1850 the program had reached a length of 14 years in 1940—requiring 4 years of college, 4 years of medical school, 1 year of internship, and 5 years of residency If no measures are taken to stop the trend, the program would reach a length of 18 years by 1970 (Reproduced with permission from The Hospital in Contemporary Life, edited by N W Faxon, Cambridge, Mass , Harvard University Press, 1949)

Careful scrutiny of many of the courses of the undergraduate medical years reveals much hidden detail that could be eliminated without losing sight of the principle that the details illustrate Does not the chemist teach the detailed steps of more enzyme reactions and demand knowledge of more formulas than are needed to illustrate the broad role of chemistry in medicine? I have already alluded to the curare drugs and the electrocardiogram Certainly there is no place in the undergraduate curriculum for those technical details of operations that the surgeon is so fond of teaching

Group teaching offers a ready solution to this problem of weeding out facts nonessential to medical education If teachers representing two, three, or four of our present departments join in giving lectures, seminars, and clinics, limits are automatically put upon the areas and facts being taught Such teaching is, of course, a form of integration Free discussion between faculty members in front of students opens less worthwhile material to criticism Checks are provided and perspective is gained We, as individuals, should subject ourselves to searching criticism, but it will be more quickly and soundly arrived at if our colleagues help us in this criticism and we in turn help them

Well-Founded Psychiatry—The second factor calling for change in teaching in the undergraduate medical curriculum is the recognition of the significance of the emotional factor in disease and the need for a more effective presentation of psychiatry The task will not be easy Mathews and Watkins[1] have said that a strong antagonism to psychiatry pervades many a medical faculty as it does the profession as a whole But the time has come to square off, face the issues, and not be led astray by ignorance or unwitting prejudice Emotional factors are to be seen and dealt with everywhere in medicine I am not speaking at the moment of the psychoses but of the gamut of conditions encountered in medicine and surgery These range from the psychosomatic diseases to the emotional factor in such everyday complaints as backache, fatigue, and the common cold

Put in other terms, the thinking mechanisms are an integral part of normal physiology and, when their balance is disturbed, the physiological disorganization may end up in somatic symptoms and changes Physiologically, there should be nothing mysterious about all this any longer The importance of getting this into our teaching is, of course, that unless treatment is directed at the origin it will be as ineffective as if the bacteria were disregarded in infectious disease

The science of psychiatry is, admittedly, in its infancy To deny it recognition in medical education because it is young and undeveloped would be as illogical as to have denied chemistry its place in medicine 80 years ago Yet many a clinician stated 80 years ago, and too many since have repeated, that chemistry and "all that science stuff" was the bunk

Sound concepts in psychiatry have emerged in recent years Experience in the teaching of these concepts, however, is still limited, and the psychiatrist lacks the confidence of the other teachers of medicine Group teaching, therefore, offers the best method of integrating psychiatry, not only into medical education but also into medicine itself

A number of medical schools are experimenting with this approach at the present time At the Harvard Medical School in 1947 the departments of medicine and surgery organized a collaborative course in "case taking" to introduce the student to the patient during the second half of the second year Three years later the psychiatrists asked to join in the teaching For the work with patients, the students were divided into groups of four or five The psychiatrist did not teach the group alone, but taught four sessions with the internist and four with the surgeon The patients seen were those on the medical and surgical wards, not those on the psychiatric ward

Opinion regarding the results was sharply divided A few of the physicians and surgeons, including senior and junior teachers, counted the time wasted Either they did not want to see what the psychiatrist had in mind or the psychiatrist did not make his objectives clear Others were enthusiastic, for they learned to see things they had not seen before, things commonly overlooked in medicine and surgery And the psychiatrist, forced by his colleagues to reduce his observations to simple terms, improved the organization of his thoughts A compromise was reached the joint sessions were not given up, but the number was reduced from eight to six

Hoard of Obsolete Therapies—The third reason for modifying the present approach to teaching the undergraduate phase of medicine is the growing hoard of obsolete modes of therapy Each generation sees new knowledge displace old therapies, but physicians are conservatively educated and cling overly long to outworn ideas As a third-year student in 1926, I was advised to learn the distribution of sciatic pain that spelled sacroiliac joint disease and for which surgical fusion of the joint was carried out As an intern, one of the most common operations I was assigned to perform was uterine suspension or ventral fixation How many of these outmoded and useless operations were performed after it became clear that they served no direct purpose? How many of today's hysterectomies and subtotal gastrectomies are really indicated? There is mounting evidence that the problems of the patients are often better treated in other ways than by such irrevocable operations

The teaching of a complicated problem such as peptic ulcer is best handled by group or integrated teaching Discussion and argument to and fro between internist, surgeon, and psychiatrist represents a winnowing by which the significant points are concentrated and outmoded concepts blown off with the wind The more frequent the discussion, the better the winnowing and the more the student learns

Issues and Dangers

What I have said thus far favors redeployment of integration and correlation as much for the education of the faculty as for that of the student The faculty needs to be jostled into a fresh look at medical education, and this is a good way

There are other seeming advantages to integrated teaching It is said that integration makes teaching more attractive and speeds the students' learning These premises are not necessarily true A dull teacher can be just as dull when teaching with others, and an inspired teacher just as scintillating when teaching alone A student may also learn just as fast or faster concentrating on a single aspect of a subject at a time What really counts at the showdown is each teacher's capacity to reach the student, to get him to organize his thinking constructively for the years ahead, and to inspire him

A principal objection raised to integrated teaching has been that it is too expensive The unnecessary duplication that group teaching eliminates does not make up for the additional cost of multiple teachers But good teaching is always expensive, and criticism, to be valid from an educational point of view, should be based on other issues Interference with faculty research, interference with the student's own responsibility for integrating, and the instability of an organization depending on voluntary collaboration are such issues

A danger of group teaching is that it may interfere with the free time of the faculty and thus with research Time schedules are necessarily a compromise No one teacher can arrange the schedule for his personal convenience and each may find his research time intruded upon Like other scientists, the medical scientist develops his most penetrating understanding when he is free and his thinking is uninterrupted The departmental structure has provided this uninterrupted time for research

Too completely integrated a course in medicine deprives the student of the responsibility for doing the integration himself As in the past, discoveries in the medical sciences will continue to be made in isolated areas If the student has not been obliged to integrate isolated facts into the whole of medicine, he will have lost an educational experience important later in his years of practice

The wholly integrated curriculum also denies the student the rewarding experience of studying an isolated science for its own sake Dr Atchley (see this issue, page 541) emphasized the value to the student of some experience in research, and this research is the opposite side of the coin Research is not done in a broad diffuse field, but deep in one area

A program of group teaching that depends upon voluntary collaboration is unstable, and this is the principal criticism of current efforts in integration A faculty committee without power of appointment depends upon good will for its effectiveness But good will is short-lived among prima donnas and busy people in general It needs constant refurbishing, and this is accomplished only by time-consuming watchfulness At Harvard, collaboration has repeatedly fallen apart since 1947 in the case taking course because no one has assumed disinterested responsibility At another medical school on the Eastern Seaboard, combined teaching clinics were instituted enthusiastically just after World War II Here too collaboration has not been without difficulty, and sometimes a clinic has passed by default to the department of medicine At Western Reserve, the several committees responsible for the new integrated curriculum are chaired, Dr T Hale Ham informs me, each by a vigorous teacher The chairman is responsible for recruiting the teachers for his special program from among the departments, the departments continuing as heretofore What will happen when the present chairmen retire remains to be seen, but without power of appointment the position of these chairmen is vulnerable from an administrative point of view The chairmen are in the position of beggars, they may recruit, but not command The great advantage of the departmental structure is, obviously, that the department head hires the talent needed, arranges a teaching schedule to fit, and knows that it will be carried out

Suggested Integration

It is my personal view that the present preoccupation with integration and correlation expresses a dissatisfaction with the organization of subject matter under the present curriculum and that we will make a mistake if we confuse this with a dissatisfaction with departmental structure per se If this be true, then we should redeploy our departments, and what I have in mind is this As it now stands there are too many departments Educational perspective has been lost by dismemberment This is certainly true of the clinical departments and probably also of the preclinical science departments No excuse can be offered for the separate departments of the surgical specialties riding off in different directions, teaching whatever comes handy, without planning All of them, including gynecology and obstetrics, should be reassembled into a single teaching department

Medicine also is too split apart, and in its integrated form it should include psychiatry One of the troubles with the teaching of psychiatry thus far has been that it has been given a chunk of the curriculum as if it were a separate subject, like ophthalmology or otology In a sense it is such a separate subject when it cares for the manic-depressive psychoses and schizophrenia If the words 'thinking processes of the patient" are substituted for 'psychiatry," then the subject is as inherent in medicine as cardiac function, and like cardiology belongs in the department of medicine The teaching of pediatrics, dermatology, and neurology should also be incorporated with the teaching of medicine

You might well ask why have I not advocated joining the teaching of surgery with that of medicine As a surgeon, I favor close relations between medicine and surgery, for we too practice medicine Integrating present-day surgery into medicine, however, is not comparable to integrating the thinking mechanisms and the emotional factors into medicine Aspects of surgery are as distinct and unfusible with most medical diseases as are the psychoses of psychiatry Like the psychoses, they are, at present, better studied and taught apart I, therefore, temper my idealism and shall be content for the time being with reintegrating surgery

The departments of physiology, pharmacology, and biochemistry teach aspects of function Would not the presentation be more effective as well as more efficient if they were joined in a division of physiology? The fecundity of research should be increased by the aggregation The growing field of biophysics would, of course, be included, indeed the division might well be headed by a biophysicist All members of the division, chemist, physicist, and physiologist, would share the responsibility for teaching general physiology The chemist would obviously emphasize chemical aspe and the physicist the biophysical

The introductory teaching of psychiatry should not be a separate course but should be included under the jurisdiction of the division of physiology. The physiologist will have to grapple with the thinking mechanism of the human being as he has with the reactions of the autonomic nervous system. The experimental physiologist Walter B. Cannon[2] described 32 years ago the bodily changes of fear, hunger, pain, and rage. In like manner, the physiologist of the future will study the higher centers of the brain—those peculiar to the human being. Productive starts have, of course, already been made. As far as present teaching is concerned, the physiologist will have to turn to the psychiatrist. Teaching together, the psychiatrist will bring such things as evidence of unconscious influences in thought and the physiologist correlations from established nervous system reflexes. This step of integrating introductory psychiatry with physiology will legitimize thinking as an honorable part of physiology and will free it of the unwarranted but delaying stigmas presently associated with the word psychiatry.

Anatomy and pathology could logically be united and bacteriology joined with them, for administrative purposes, in a division of morphology and microbiology. All three subjects deal with morphology. Much o pathology and bacteriology, particularly immunology is vividly functional and would secure to the entir division the spur so essential to spirited investigation.

Finally, these condensations or integrations shoul not destroy the strong advantages of the present departmental structure, and yet they should afford th needed means of pruning the facts taught, of introducing the thinking mechanisms into the pathologica physiology of disease, and of ridding the curriculum of obsolete therapies.

THE UNDERLYING CAUSE OF UNREST IN UNIVERSITY MEDICINE

W. Barry Wood Jr., M.D., Baltimore

• *Medical science has been increasing rapidly in scope and complexity. Medical research has to enlist the services of the whole range of knowledge from surgery to mathematics, and medical practice depends on techniques ranging from physics to psychiatry. As a result, the duration and expense of medical education have increased greatly. The eventual solution of the basic problem must include some shortening of the course for selected medical students, some reduction of the now almost prohibitive cost of medical education, closer collaboration between liberal arts and medical science, and strengthening of the basic science departments of medical schools.*

The most striking characteristic of present-day medicine is its state of intense ferment. A climate of unrest pervades the profession. The uneasiness that is evident on all sides relates not only to our system of medical education but also to medical practice. What, may we ask, is the underlying cause of this unrest?

Some would doubtless attribute it to the upheaval in medical economics, which has been brought about by the rapid expansion of health insurance, and to the phenomenal growth of hospitals, which has stretched to the breaking point the available supply of professional personnel. Others might blame it on the increasing trend toward group practice and the growing strength of full-time staffs in the clinical departments of medical schools and hospitals. Still others would point to the changing pattern of disease, which has resulted from the control of infectious agents, the general increase in longevity, and the new health hazards of an industrial civilization.

In my opinion none of these factors is primarily responsible for the present state of ferment in the medical profession. Rather it would seem to me that the real cause of our present unrest is the rapidly changing dimensions of medical science. It is these that I should like to discuss very briefly. In so doing, I shall make analogies to the conventional dimensions of Euclidean geometry, namely, depth, breadth, and length. The Einsteinian fourth dimension of time will also be drawn into the discussion.

Depth in Medical Science

Let us begin by considering the depth of medical science. The rapidity with which this dimension is changing is best illustrated by a comparison of two outstanding examples of medical research: one reported from Germany approximately 100 years ago,[1] the other published by American investigators within the past few months.[2]

The first of these examples resulted from the prodigious labors of Prof. Carl A. Wunderlich, head of the medical clinic at the University of Leipzig. At the time that his meticulous investigations were begun, medical thermometry was an unknown subject. Although the thermometer had been discovered several decades earlier, it had never been systematically applied to the study of disease. Wunderlich, accordingly, began to make frequent measurements of body temperature on all patients admitted to his hospital clinic. Over a period of five or six years, he thus studied more than 25,000 patients with a wide variety of dis-

Vice President, the Johns Hopkins Medical Institutions.

Read before the 53rd Annual Congress on Medical Education and Licensure, Chicago, Feb. 11, 1957.

eases His carefully kept records revealed all the important relationships that are now known to exist between body temperature and the clinical course of the commonest forms of illness These relationships are clearly set forth in his now famous monograph, entitled Relationship of Medical Thermometry to the Course of Human Disease" Published in 1862, it had a profound effect upon medical practice all over the world From it clinicians learned for the first time the true value of the medical thermometer

As we look back upon Wunderlich's contributions we cannot help but be impressed by their significance Yet, measured by present-day standards, his studies were purely descriptive, though of vast importance, they were relatively superficial They made no attempt to get at underlying causes, they merely described the changes in body temperature that take place during illness And yet they stand today as one of the major medical contributions of the mid-19th century

Contrast the superficiality of Wunderlich's approach with studies recently reported in the *Journal of Experimental Medicine* relating to the genetics of individual mammalian cells [2] This work, carried out at the University of Colorado, has involved the use of a tissue culture method that makes possible, for the first time, the same kinds of studies on individual mammalian cells that bacteriologists have been making for years on various species of bacteria There are two keys to the new experimental technique The first involves the use of the enzyme trypsin to dissolve the proteinaceous intercellular cement that causes mammalian cells always to grow in sheets in tissue culture rather than as individual cells The second has to do with the biochemical conditions in the culture medium, which, it has been found, can be made optimal by the presence of a 'feeder' layer of metabolizing but nonmultiplying cells

Through these two ingenious innovations, it is now possible to grow single mammalian cells on semisolid mediums in ordinary Petri dishes Each cell placed upon the medium eventually grows into a colony easily visible to the naked eye The number of cells in each colony can be counted, and thus the rate of cellular division can be accurately measured The method is exactly analogous to that used in studying the reproductive behavior of bacteria Its discoverer, Dr Theodore Puck, has already applied it to an analysis of the mechanism of action of ionizing radiation upon human tissue cells Certainly in this age of atomic power there is no subject concerning which humanity is more in need of specific information

Puck's findings may be briefly summarized as follows First, he has shown that cells derived from a human cervical cancer (the so-called HeLa cells) are many times more sensitive to x-rays than are any other micro organisms that have previously been studied In fact, the amount of radiation needed to stop the multiplication of a single HeLa cell is so small that it could not possibly break more than a few chemical bonds in the cell This quantitative evidence strongly suggests that the radiation acts upon the cellular reproductive apparatus, namely, the gene-containing chromosomes

Secondly, the observed relationship between the dose of radiation applied and the percentage of survival of cells follows what is known as a typical "two-hit" curve This fact suggests that the x-rays act upon the chromosomes of the cell rather than upon any single gene

Thirdly, whereas small doses of radiation will cause only a delay in growth, somewhat larger ones cause the growth to cease after several generations When the dose of radiation is increased still further, multiplication stops immediately, but the surviving cells continue to grow in size and eventually become giant cells, which metabolize actively and are highly susceptible to virus action, in spite of the fact that they do not reproduce Finally, it has been shown that only with very large doses can complete disintegration of the HeLa cells be achieved

These remarkable studies of Puck vividly illustrate the increasing depth of medical science For here, in contrast to the workers of Wunderlich's time, is a medical scientist probing directly at the very secrets of life itself Such probings require a depth of knowledge in the life sciences that Wunderlich could hardly have dreamed of Surely the thesis that medical science has grown, and is continuing to grow, in depth need not be belabored further

Breadth in Medical Science

Equally impressive has been its growth in breadth If I may continue to refer to Puck's work for a moment longer, I should like to point out that he is by training a physical chemist, rather than a physician In carrying out the work that I have briefly described, he has had to make use of many disciplines

The following points in this regard are of interest First, the cells that he used in the tissue-culture experiments were originally derived from a cancer of the cervix in a human Second, in designing his tissue-culture method he borrowed heavily from conventional bacteriology Third, he made use of a biochemical method to separate individual cells for culture Fourth his knowledge of physics aided him in interpreting the biological effects of the x-rays Fifth, consideration of the quantitative effects of the x-rays involved the use of thermodynamics Sixth, his work led him primarily into a problem of genetics And, finally, a fairly complicated method of mathematical analysis was necessary to interpret fully the relationship between x-ray dose and cell survival

Here, then, is a single example of modern medical research in which the principal investigator has made use of information derived from surgery, microbiology, biochemistry, physics, genetics, and mathematics The possible practical application of these studies cannot yet be evaluated Suffice it to say that the studies may well prove to have a bearing upon the understanding of such basic biological problems as those of organ differentiation, the development of congenital defects, the nature of malignancy, the biological effects of radiation, and the intermediary metabolism of individual tissue cells

Many other examples might be cited to illustrate the fact that modern medical science encompasses all of the basic natural sciences But what of the social sciences? Certainly modern medicine involves them also No physician can fully understand his patients unless he is reasonably familiar with all of the possible environmental factors of illness Indeed, medicine can perhaps best be defined as a study of the interaction of man and his environment The important environmental variables that influence his well-being include not only physical and chemical factors but social forces as well Through psychiatry, particularly, modern medicine has become deeply involved in the social sciences, including such disciplines as social anthropology and social psychology That medical science is far broader today than it ever was before is evident to even the most casual observer

Length in Medical Science

Now you will ask, how in the world am I going to drag into this discussion the third Euclidean dimension, namely, length If you will allow me a little liberty with my analogy, I should like to introduce not only the concept of length but also that of time For to me the most important practical problem that confronts medicine today is that created by the excessive length of time required to train a modern physician

As the depth and breadth of knowledge in medical science have increased, the combined undergraduate-postgraduate courses in medical schools and hospitals have become longer and longer In this country, physicians and surgeons are considered well qualified to practice only after they have completed 4 years of college, 4 years of medical school, and an additional 3 or more years in a hospital—a total of at least 11 years after high school When two years of compulsory military training are added, many doctors of medicine have reached the age of 30 before they have finished their formal education Those interested in research have spent a number of their most promising years merely preparing for their careers This demanding period of training, with its inevitable economic strain, has become so long that it is beginning to discourage candidates from entering the field of medicine The relative number of students applying for admission to medical schools as compared to those applying for training in other professions, has been definitely on the decrease [3] Furthermore, there is good evidence that the excellence of practicing doctors is related, in part at least, to the length and quality of their postgraduate training as house officers Under the present prolonged curriculum of undergraduate medical education, many young physicians are forced, for economic reasons to enter private practice before they have gained adequate experience in hospital residencies Such short-cuts to practice, in this age of expanding science, deprive society of the maximal return on its investment in medical manpower

Comment

Is it surprising, then, that we as physicians sense within our profession a climate of unrest? The basic problems that face medicine today are the direct result of the changing dimensions of medical science These problems will not be solved overnight, nor will they be solved in the same way in every institution Their eventual solution will require wise and imaginative planning on the part of those involved in medical education, in the running of hospitals, and in the practice of medicine

In an attempt to meet them effectively in our own university, a committee of the medical faculty, working jointly with a small committee from the faculty of philosophy, formulated last year an extensive revision of the educational program of the school of medicine It would not be appropriate for me to attempt to outline in any detail the proposed plan for the medical school I would, however, like to state its long-range objectives They are, very briefly, as follows (1) to attract a greater number of talented students to the study of medicine by (*a*) shortening the course of training for selected students by two years and (*b*) cutting accordingly the now almost prohibitive cost of their medical education, (2) to break down the presently existing barrier between the liberal arts and the medical sciences, and thus not only liberalize the training of medical students but also bring the school of medicine into closer collaboration with the rest of the university, and (3) to add strength to the basic science departments of the medical school, on the grounds that these departments must, in the final analysis, provide the foundation of clinical medicine and public health Whether these ambitious objectives can be attained remains to be seen They stand at present as an impressive challenge to the faculty and students of the school of medicine

In conclusion, I should like to comment briefly on what we so casually refer to today as "university medicine' Its true significance is perhaps best illustrated by the following quotation from Sir Francis Fraser's prophetic lecture entitled 'The Changing Foundations of Medicine' [4]

> While clinical medicine continues to depend to an increasing extent on physiology and biochemistry, it is looking now for its inspiration and its methods especially to the work of the physicist, the chemist and the biologist Without an understanding of these sciences and their recent advances it is difficult to assess the value of much of the new work being carried out in clinical science and being applied to the practice of medicine In other words these subjects can no longer be regarded as *pre medical* in our scheme of medical education, but rather as *pre clinical* along with anatomy, physiology, biochemistry, pathology, bacteriology and pharmacology

Thus it is evident, as Professor Fraser so clearly states, that the changing dimensions of medical science are drawing medical schools closer than ever to their parent universities The degree to which this university bond is strengthened will determine in no small measure the future progress of medicine

RESEARCH KNOWLEDGE AND ATTITUDES REFLECTED IN MEDICAL EDUCATION

Edward W Dempsey, Ph D, St Louis

• *Teachers who are also competent as investigators are no longer confined to the basic science departments of medical schools but are found in the clinical departments as well Students can obtain desirable research experience by various informal and formal arrangements, which include programs of summer research or even a year of full time research in a laboratory of the student's choice after he has finished his preclinical courses The financial problems can be solved Grants to institutions that wish to further student research training are available through federal agencies and private foundations These permit the universities to pay students enough for time spent on research to compensate them when they forego higher paying work of other kinds*

Much that I might have said has already been stated by Drs Weiskotten, Whitehorn, and Atchley (this issue, pages 533, 538, and 541) It seems to me that their comments constitute a most eloquent plea for the furtherance of research training during the time medical students are enrolled in our medical schools They are also a testimony to the effectiveness of such teaching in furthering the ideals of the medical profession Consequently, I think now that it is unnecessary for me to defend the point of view that furtherance of our research training is a desirable thing

I might, however, reiterate some of the comments that have been made It might be recalled, for example, that Flexner said, in his report on medical education, that there is not, or ought not to be, any essential difference between the attitude of mind of the scientist and of the clinician Both should be people trained to observe, to reflect on their observations, and to draw tentative conclusions on which they then could base, respectively, an experimental procedure or a therapeutic regimen Following this intervention, a second period of observation, reflection, and conclusion should be undertaken In both the experimental and the clinical situation, the mental attitudes are identical

I would like also to reiterate what has been said earlier, that the clinical research undertaken by medical students during the time they are in medical school, especially in their clinical years, and the use of the methods evolved by and practiced in the basic science departments have formed one of the principal integrating forces in medical education The activities of such students has brought the basic science teachers closer to those operating in the clinical departments than perhaps any other single force operating in the medical educational institutions of today

So I take it, then, that we can begin with an agreement that research training for medical students is an admirable thing The questions remain as to how this training may be implemented most effectively and what special problems, financial, organizational, and otherwise, such a program entails for the medical schools These problems are interrelated with some others that concern both medical schools and medical practice, the problems of recruitment of teachers in medical schools and the dissemination of the results of research to the profession Obviously, the larger the number of trained investigators who emerge from medical schools the more rapid and the more skillful will be the introduction of future experimental results into clinical practice

Forty to 50 years ago laboratory teaching of the type now standard in all schools was recognized as a desirable thing Gradually, one school after another instituted laboratory teaching, with staffs of basic science instructors Courses were introduced that replaced the previous didactic exercises At first there was a small number of such schools A generation later, about the time that I began to be concerned with medical education, the teachers trained by those original schools had taken effective places in a larger number of institutions Today, with another generation, one finds that a large number of medical schools scattered all over the United States are now staffed by instructors who are thoroughly competent as investigators, and these investigator-teachers are no longer confined exclusively to the basic science departments They are to be found in the clinical departments as well There is now a continuing thread of interest in the investigative attitude and approach that begins from the moment the student enters the medical school and, in most instances, continues far beyond his graduation

As this increase and spread of talent has been accomplished, there has been a similar increase in the variety of investigative training undertaken by the different schools One of the most interesting and exciting things about American medical education is its capacity for producing a variety of people who can meet the needs of various local situations and take advantage of the opportunities to be found, while discounting the difficulties that arise in particular local settings

In any event, a number of tactics have been evolved in the medical schools Lectures are no longer the kind that used to be given For instance, in my own

---

Professor of Anatomy, Washington University School of Medicine

Read before the 57th Annual Congress on Medical Education and Licensure, Chicago Feb 11, 1957 field, anatomy, it had been the tradition for centuries that lectures were to be orations This is no longer true Lectures in most of the departments of anatomy today are concerned not so much with a recitation of fact presented as palatably as possible as with a discussion of the experimental aspects of the subject and an introduction of the experimental material in current journals, which has not yet been incorporated into the textbooks

Tutorial systems have been introduced in many schools, sometimes under quite informal guises and in other instances in semiformal arrangements brought about spontaneously by the desire on the part of the staff and of the students to engage in informal meetings to discuss experimental work

Research Opportunities

A number of schools have instituted programs of summer research This type of program developed more or less spontaneously, by virtue of occasional students approaching staff members and suggesting to them that they were interested in doing some of the kind of work with which the instructors were identified Out of this kind of casual, incidental, and spontaneous association there has arisen more recently a formalized program at many institutions, whereby funds have been sought to make it possible to encourage students to undertake such activities A few years ago the United States Public Health Service made it possible to obtain grants for this purpose, and this has immeasurably furthered the development of student research activity

The summer research program has been criticized by a number of people as being superficial because the period is too short for the best results It is certainly true that research training should not be superficial It is, however, also true that the job of capturing the imagination and attention of the student is one that must be undertaken at the appropriate time, and the appropriate time is always the time when the imaginative idea has occurred in the student's mind So, for purposes merely of introducing the student to the exceptional intellectual opportunities in medicine, I think this program is well justified

Still other opportunities are available Many institutions encourage occasional students to take off a year from their regular medical studies This year normally occurs after the completion of the preclinical courses The student is encouraged to spend the year doing full-time research in the laboratory of his choice In many institutions this device has worked very well indeed

In listing the support available for student research training, one should also mention the postdoctoral fellowship, which, although available after the student has received his M D degree, is still used at a time when he is a relative beginner in investigation Therefore, these fellowships afford an opportunity to undertake serious and sustained work in a laboratory under the direction of a skilled investigator

There are characteristics common to all of these programs, which have been developed in their various ways and in response to spontaneous demands—sometimes on the part of the student and sometimes on the part of the faculty, who require, to some degree, a close contact with students to help them acquire a sense of fulfillment in their occupations The programs all cost money They occupy a considerable part of the time of the faculty and of the student I believe these two factors have caused much difficulty in the advancement of the programs It is inescapably true that the medical curriculum is full, that a great many new facets of knowledge have been developed in recent times, and that clearing curricular time at the expense of completeness is not entirely justifiable Nevertheless, a way can be found, as a way has been found with these spontaneous programs, to make at least a beginning toward an improved method of launching students into investigative work And, as such programs develop, I am confident that clearance of the time from the curriculum will be possible to an even greater degree

The financial aspects of the program are not great at the present However, they are still troublesome With the present degree of research activity in medical institutions, in most cases it is possible for the laboratories to make places for the occasional students, or groups of students This represents a secondary use of facilities that have been accumulated primarily for other purposes Through the activities of the federal agencies and the private foundations, it has also been possible to obtain grants-in-aid These grants permit the universities to pay students enough for time spent in research during the summer, preventing the necessity of their obtaining higher-paying jobs

Specifically, I should like to mention here a new program that the Public Health Service is initiating An Experimental Training Grants Committee has been formed, with money available for grants to institutions that wish to further student research training This committee has adopted a policy that the furtherance of a variety of kinds of research is advisable In other words, there is no simple plan that could and should be enforced as the ideal plan for all medical schools

I mention this to indicate the awareness of the usefulness of this program on the part of the agencies interested in furthering medical research and education This information is evidence that the spontaneous evolution of the investigative approach to the teaching of medical students, bringing the student-teacher relationship into the research laboratory, has been continuing in the United States I am confident it will continue over the foreseeable future I have great confidence that, in this program, the advantages mentioned by Dr Weiskotten (see this issue, page 533) as accruing from the medical revolution of the past will continue to operate in the future generation

CLINICAL NOTES

SEFUL PRECAUTIONS IN RADIOGRAPHY FROM THE GENETIC POINT OF VIEW

Israel E Kirsh, M D, Hines, Ill

The recent report[1] of the National Academy of Sciences–National Research Council concerning the bio gical effects of atomic radiation was quite reassuring s to the fall out from nuclear weapon tests but raised n alarm in regard to the medical use of x-rays The edical use of x-rays should be reduced as much as is nsistent with medical necessity ' reads one of the commendations of the genetics committee of the uncil, headed by Dr Warren Weaver vice-president r natural and medical sciences of the Rockefeller oundation

As a consequence of this report, given out at a press nference[2] on June 12 1956, there may be some pub anxiety on the subject of x-rays This situation con rns not only radiologists but physicians in general, ho find x ray studies increasingly valuable and who w are expected to reconsider them in terms of their lue versus their danger

For example, it was advised by the genetics com ittee that *individuals up to the age of 30 years re ive* a total accumulated dose to the reproductive lls of not more than 50 r and that not more than an ad tional 50 r be given to individuals up to 40 years of ge For the population as a whole, the average ex sure of the reproductive cells to radiation (above e natural background) should be limited up to the ge of 30 years to 10 r

Also in June, 1956, the report of the British Medical esearch Council on Nuclear and Allied Radiation[3] as announced Its conclusions were much the same as ose of the National Research Council *in the United ates The British group found that the amount of* diation reaching the reproductive organs of the Eng h people through diagnostic radiology was much the ost prolific source of artificial irradiation and that the sk of genetic damage from test explosions of nuclear eapons was negligible They called for a review of dications for diagnostic x-ray procedures and a check of conditions under which they are carried t, *from* the radiation point of view They advised critical examination of the use of radiotherapy in nmalignant conditions Specifically, the danger of ducing leukemia following radiation of the whole dy was noted The evidence consisted of experi ents in animals, the incidence of the disease in iroshima and Nagasaki after the atomic bomb ex losions, and the increased number of cases of the sease after x-ray therapy in cases of rheumatoid ondylitis

Because of an appreciation of the value of the work on mutations and radiation by Muller,[4] I was able to anticipate some of these warnings and, some time ago, pointed out in THE JOURNAL[5] that two simple measures were effective in decreasing the radiation in x-ray procedures They are use of adequate aluminum filters in the radiographic machines and fluoroscopes and of lead-rubber protective shields placed over the genitals during radiography

Protective Shields for the Genitals

Since the publication of that paper, I have found that there was an objection to the use of the lead-rubber shield in that it tended to slip *somewhat and* might then obscure bony structures of interest A change was made to plain sheet lead of 1 5-cm thickness This was satisfactory, because it could be molded readily to fit over the genitals and remained in place during the examination When these shields were *placed on male patients, no radiation could be meas*ured on the r-meter placed on the scrotum in various x-ray procedures Therefore, the lead shields have convenience and effectiveness to recommend them in the case of most patients in veterans and military hospitals as well as in 50% of the patients in general hospitals (This is not readily applicable for female patients)

Adequate Filtration

The value of adequate filtration in x-ray diagnostic equipment has been shown in the past by eminent authorities[6] in radiology and physics However, my discussion[5] of the subject was made brief and nontechnical in order to influence physicians who, although not experts in radiation, use x-ray machines and fluoroscopes Manufacturers of x-ray equipment are now increasingly installing filters in effective *amounts* (3 mm Al *in fluoroscopes* and 2 mm in radiographic machines) rather than the traditional 0 5 mm Al, which might be called token filtration

A question asked at the press conference[2] at which the National Research Council report was given out deserves a serious answer The question was In view of the large number of people who receive some radiation in this way, should the chest x-ray survey program for tuberculosis be stopped? The experts at that time did not give a direct answer In order to have the basis for an answer, it is necessary to know how much radiation the gonads receive in the course of a chest x-ray

Measurements of such radiation were made at the Veterans Hospital, Hines, Ill, with the use of the conventional chest film and a survey-type photoroentgen

---

From the Department of Radiology, Veterans Administra on Hospital chest examination (two 'stereo" films) A Victoreen r-meter was used for making the measurements This was a freshly calibrated instrument having a scale reading to 250 mr in steps of 5 mr, thus permitting readings to the nearest 1 mr, and made for use in the 60-to-400-kv range When the exposure was to be made, the roentgen meter, clamped on a pedestal, was placed between the thighs in contact with the posterior aspect of the scrotum There was a 2-mm Al filter on the radiographic tube A high-kilovolt technique (110 to 125 kvp) is routinely employed for chest radiography, and a thin stationary grid is placed between the patient and the cassette Slight variations in exposure factors, because of differences in the size of the patients, will not be discussed in detail here The measurements obtained are shown in table 1

It will be noticed that the large cone placed on the radiographic tube did not decrease the radiation on the gonads (table 2) A smaller cone of the 'double-diaphragm' type was then placed on the tube In no case was any radiation obtained on the scrotum when this cone was used

The large radiographic cone first used had an aperture of 11 5 cm (diameter) The small cone was of the "double-diaphragm type and had an aperture of 8 cm The manufacturer states that it contains more than the usual amount of lead, being designed for radiography up to 125 kv The small cone is now used exclusively at the Veterans Hospital in Hines, Ill At the 72-in distance, the transmitted beam fully covers the 14-by-17-in film

It is evident, therefore, that the use of a cone will considerably reduce radiation on the gonads in chest roentgenography, but it should be noted that a large cone at such a distance is no better than no cone at all The cone has to limit the beam adequately to be of any use

Comment

It is probably wise to reappraise such things as routine preemployment x-rays of the lumbar spine in the absence of symptoms[7] Reconsideration is also due for such occasional practices as very extensive roentgenologic examinations in the pelvic region, including the taking of multiple views, the habitual taking of stereoroentgenographs, and the frequent repeat x-rays on patients on a time schedule rather than on the basis of specific individual need

TABLE 1—*Amount of Radiation to Gonads Received in Course of Chest X-ray in Three Male Patients*

	Ordinary Chest Film r				Photoroentgen Examination (Two Stereo Exposures) r	
	No Limiting Cone		Large Cone			
Case No	Chest	Scrotum	Chest	Scrotum	Chest	Scrotum
1	0 030	0 011	0 036	0 011	3 0	0 020
	0 0[illegible]2	0 018	0 067	0 009	4 0	0 016
3	0 078	0 019	[illegible]	0 0[illegible]2	3 6	0 018

A relevant fact concerning x-rays in this region is that the radiation reaching the scrotum in an ordinary x-ray (anteroposterior and lateral views) of the lumbosacral spine is 6 5 r with no filter and 1 7 r with a 2-mm filter[5] It is to be remembered that, in the male patients studied, a lead shield over the scrotum eliminated the radiation, so that it did not register on our milliroentgen meter

TABLE 2—*Amount of Radiation to Gonads Without Limiting Cone and with Large Cone on Radiographic Tube in Course of Chest X-ray in Three Male Patients*

		Dose on Scrotum r	
Case No	Dose on Chest r	No Cone	Large Cone
4	0 030	0 021	0 021
5	0 030	0 012	0 015
6	0 038	0 020	0 019

* No dose with small cone

Such data as those given above should be available for various x-ray examinations They should be studied by all those using and recommending x-rays, in the light of current interest in the relation of radiation to genetics

Summary

The current increased interest in radiation due to nuclear weapons has stimulated a new look at radiation in diagnostic radiology from the genetic point of view Ionization chambers placed on the scrotum can be easily used to measure approximately the amount of radiation reaching the genitals in diagnostic procedures in male patients The radiation is reduced significantly by the use of filters and limiting cones in radiographic machines and fluoroscopes Cones are without value unless they are small enough to keep the direct beam away from the genitals In male patients, lead shields on the genitals reduce gonadal radiation to insignificant levels

603 N Cuyler Ave, Oak Park Ill

Mr Wallace Bergeron Chief Technician, X-ray Therapy Department Veterans Administration Hospital, Hines, Ill, made the radiation measurements used in this study

COUNCIL ON FOODS AND NUTRITION

Report to the Council

The following paper was presented at the symposium, 'The Relation of Proteins and Amino Acids to Human Nutrition,' in Los Angeles, May 21, 1956 This symposium was sponsored by the Council on Foods and Nutrition, with the cooperation of the Los Angeles County Medical Society and the School of Medicine, University of California at Los Angeles This report is the fourth of the series, which will be available in monograph form

Philip L White, Sc D , *Secretary*

KWASHIORKOR IN CHILDREN AND ITS RESPONSE TO PROTEIN THERAPY

Nevin S Scrimshaw, M D Ph D , Moisés Behar, M D , Guillermo Arroyave, Ph D , Carlos Tejada, M D
and
Fernando Viteri, M D , Guatemala, Central America

In its severe form, protein malnutrition is most frequently seen today in young children Under the name of *sindrome pluricarencial de la infancia* (S P I) in the Spanish-speaking countries and kwashiorkor in most other parts of the world, a well-defined protein deficiency syndrome is common in children 1 to 5 years of age in most underdeveloped areas of the world The condition begins to develop as soon as the quantity of protein contained in the mother's milk becomes inadequate for the needs of the growing child The amount of protein obtained by the nursing infant becomes inadequate sometime after the 8th to 10th month This inadequacy steadily increases until the time of weaning, when the child is likely to receive a diet containing a high proportion of carbohydrate and little or no protein of animal origin During this period, the growth and maturation of the child are greatly slowed If they are fortunate, children in the lower economic groups in underdeveloped areas pass through the pre-school period with little additional external evidence of damage and resume more normal growth and development when they reach school age Unfortunately, many of these children with underlying protein malnutrition do not escape more serious consequences, they develop the severe protein malnutrition snydrome of kwashiorkor and die from it

Factors Associated with Development of Clinical Kwashiorkor

Any one of several factors may precipitate the acute episode of kwashiorkor in a child already suffering from malnutrition [1] One of the commonest is infectious diarrhea, which not only interferes greatly with the child s absorption of nutrients and increases his loss of body proteins but also may cause the mother to further restrict his diet Frequently the child is given a starchy solution such as rice water or corn starch gruel containing essentially no protein, and strong purgatives are administered to rid him of the worms that the mother mistakenly believes are causing the diarrhea With such treatment the child is likely to develop frank symptoms of kwashiorkor in two to four weeks

Other precipitating causes of kwashiorkor in an already malnourished child may be an attack of some infectious disease such as measles or whooping cough, an emotional shock such as the death of a parent, or a worsening of the economic condition of the family At times the basic diet is so poor that the child gradually develops kwashiorkor without any other identifiable precipitating cause

Characteristics of the Acute Syndrome

Clinical Findings —Retarded growth and development as initial clinical characteristics of the syndrome have already been mentioned Psychic changes include profound anorexia, apathy, and, frequently, irritability Muscle tone is decreased, and edema may often be severe The skin changes include atrophy of the skin appendages, areas of hyperkeratosis, and altered pigmentation The skin lesions are suggestive of those of pellagra but are not confined to areas exposed to sunlight Secondary infections may result in the development of extensive excoriations The hair is likely to be thin, brittle, and pale and sometimes acquires a reddish cast It is frequently sparse and usually can be pulled out easily Changes in the nails often parallel those in the hair Various other clinical signs and symptoms associated with concomitant specific vitamin and mineral deficiencies may be present but vary from one region to another

Pathology —The pathological changes found at autopsy in fatal cases are often so severe that it is inconceivable that they have come about in the relatively short period of time after either the occurrence of a precipitating cause or the onset of the clinical signs and symptoms [2] This is taken as further evidence for belief in the widespread existence of an underlying severe malnutrition in underdeveloped areas, even in children who do not manifest the clinical characteris-

---

From the Institute of Nutrition of Central America and Panama (INCAP) tics of kwashiorkor In addition to the lower body weights, most of the organs are grossly underweight, and a monolobular reticulosis of the liver that has taken a relatively long time to develop is seen in about 20% of the cases

In acute kwashiorkor, the liver is enlarged and shows a fatty change that is often so severe it involves almost every cell and obliterates the lumen of the sinusoids In some cases the pancreas may be enlarged rather than underweight, but the pancreatic acini always show moderate to severe atrophy and a reduction in the number of secretory granules Fibrosis is likely to be present in the pancreas and may be severe Atrophy of the intestine and stomach occurs, it may be very pronounced and associated with a gross dilatation of these organs

The skin and skin appendages show a marked degree of atrophy, as do also the follicles of the thyroid In the latter case, there is a loss of colloid substance and an increase in interstitial fibrosis The skin shows hyperkeratosis and parakeratosis over the area of gross lesions Atrophy and loss of lipids are apparent in the adrenal cortex, and fatty degeneration of the kidney tubules may be present

Hematological Findings —The characteristic anemia appears to be normocytic or mildly macrocytic, and the bone marrow shows relative hypoplasia of the erythroid series [2a] When hookworm or other conditions producing iron deficiency are present, the child with kwashiorkor may have a hypochromic microcytic anemia with no hypoplasia of the marrow

Biochemical Alterations —The positive biochemical findings have been reviewed recently [3] They include the low activity of the serum enzymes amylase, esterase, lipase, and alkaline phosphatase as well as of the enzymes lipase, amylase, and trypsin in the duodenum Total serum protein and albumin levels are both greatly lowered, although the relative amounts of alpha$_1$ globulin and gamma globulin seem to be somewhat increased The values of serum vitamin A, carotene, and vitamin E tend to be very low, those of riboflavin are within normal limits, whereas those of ascorbic acid are usually lowered in the acute disease Blood serum calcium and phosphorus levels are little altered, but low serum levels have been reported for cholesterol, phospholipids and urea, whereas the total serum lipid levels and the ratio of free to total cholesterol appear to be high Kwashiorkor is also associated with low blood serum levels of potassium,[4] but this may be due primarily to the diarrhea

Physiological Changes —Nitrogen retention has quite naturally received considerable attention because kwashiorkor develops as the result of a prolonged negative balance All workers agree that the nitrogen balance becomes strongly positive whenever protein is given in the acute phase of the disease Children with kwashiorkor also retain a higher proportion of the total nitrogen of the diet than do well-nourished children [5] The only information on amino acid metabolism shows a reduced excretion of threonine in the urine and higher than normal ratios of isoleucine to leucine and of phenylalanine to tyrosine [6] Fat retention is lowered,[7] and steatorrhea is usually encountered

Altered kidney function is indicated by the frequency of oliguria, and altered cardiac function is indicated by electrocardiographic changes The latter changes include a profound diminution in the amplitude of all deflections and occasional prolongation of the QT interval [8] There is no information on initial endocrinological changes, unless the oliguria is considered to be caused by a failure of the liver to destroy antidiuretic hormone as is suggested by Gopalan [8]

Effect of Protein Therapy

The foregoing review of the characteristics o kwashiorkor has been intentionally brief, since mor complete recent reviews are available [3] The princip purpose of this article is to summarize the effects protein therapy on these initial findings

Disappearance of Clinical Signs —When dried ski milk or half-skim milk alone is given, most of t findings show rapid change In the first 7 to 10 day if the child responds to therapy, the apathy and i tability largely disappear and the child's appe returns Edema largely or entirely disappears, the s lesions clear up obviously, new hair and nail substa begin to grow with good color and texture, and muscle tone improves

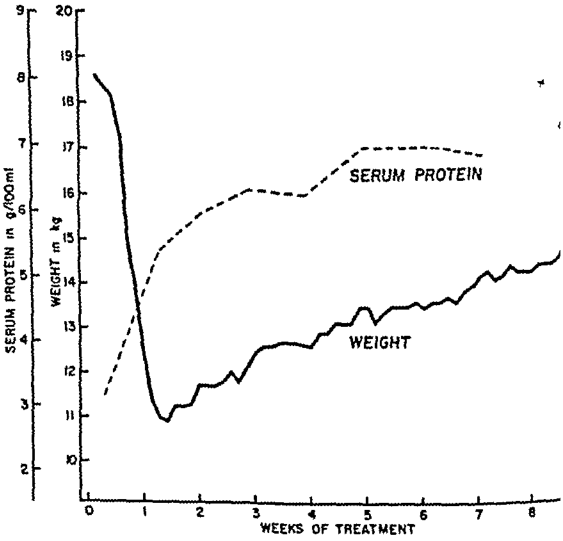

Fig 1 —Serum protein and weight changes in recovery f kwashiorkor in girl 6 years, 6 months old

Under ideal conditions, the weight drops rapidly edema is lost but then begins to climb (fig 1), the diarrhea stops promptly The remarkable cha in appearance when severe edema is lost is illustra by the child in figure 2 The boy in figure 3 shows recovery, which occurred in 10 weeks of dietary tre ment In less favorable cases, possibly associated w cross infections caused by poor hospital conditi and lowered resistance, intermittent diarrhea cont ues for many weeks, and the child fails to gain weight during this extended period

Considerable evidence is available to suggest that with reasonable isolation of patients and care to avoid cross infections, most children who recover will do so without the long stationary period in weight It should be added that some children fail to respond to any kind of therapy grow rapidly worse and die In these patients the biochemical and pathological changes described earlier seem to have progressed too far to be reversed Fortunately these cases are in the minority

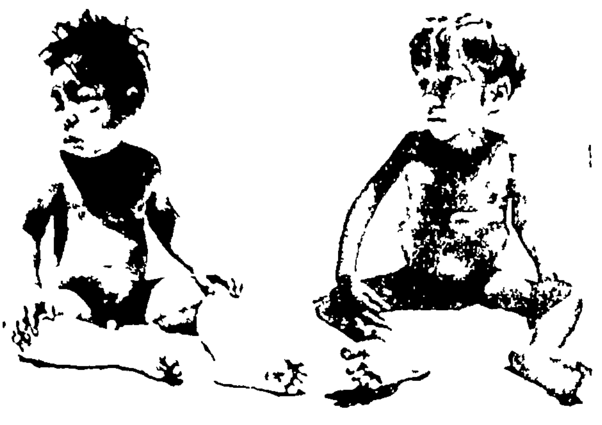

Fig 2—Boy 3 years 10 months of age showing (*left*) kwashiorkor with severe edema Five weeks later (*right*) when edema has been lost, considerable degree of undernutrition is revealed

Hematological Response—When the mild macrocytic anemia of kwashiorkor is uncomplicated by hookworm or other conditions directly affecting iron metabolism, it responds rapidly to the administration of milk alone Figure 4 illustrates the prompt reticulocyte response and rapid increase in red blood cell count In our cases however, if supplementary iron is not given, a microcytosis develops that can be corrected by the oral administration of iron, which will produce a second reticulocyte response These changes are accompanied by a renewal of erythroblastic activity in the bone marrow When microcytic anemia is present initially, supplementary iron must be given from the beginning if a satisfactory hemopoietic response is to be obtained

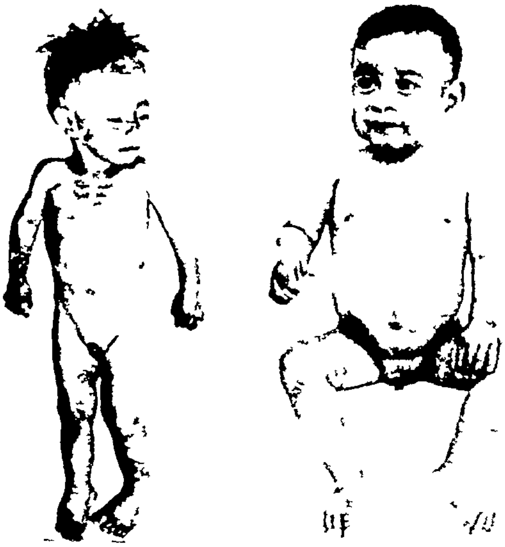

Fig 3—Boy 2 years, 3 months of age showing edema skin lesions, and other characteristics of kwashiorkor (*left*) Ten weeks later (*right*) good recovery occurred with dietary treatment alone

Pathological Changes—Of the reversible pathological changes, only those in the liver can be studied conveniently From both autopsy and biopsy specimens we know that nearly all the liver cells contain excessive fat in the acute stage of the disease and that the sinusoids are obliterated by the swelling of the cells Within 3 to 14 days of optimal dietary treatment, this extra fat disappeared in our cases Figure 5 shows the microscopic appearance of a biopsy specimen of the liver, with partial disappearance of fat, obtained five days after admission in a child with an acute case of kwashiorkor Since fat disappears in the opposite order in which it is laid down, the cells in the center of the lobules are the first to lose their fat In most cases, when stained with a reticulum stain such as Gomori, the liver shows a mild to moderate reticulum fiber proliferation This persists for as long a period of time as we have been able to follow cases, at present a maximum of 15 weeks (fig 6)

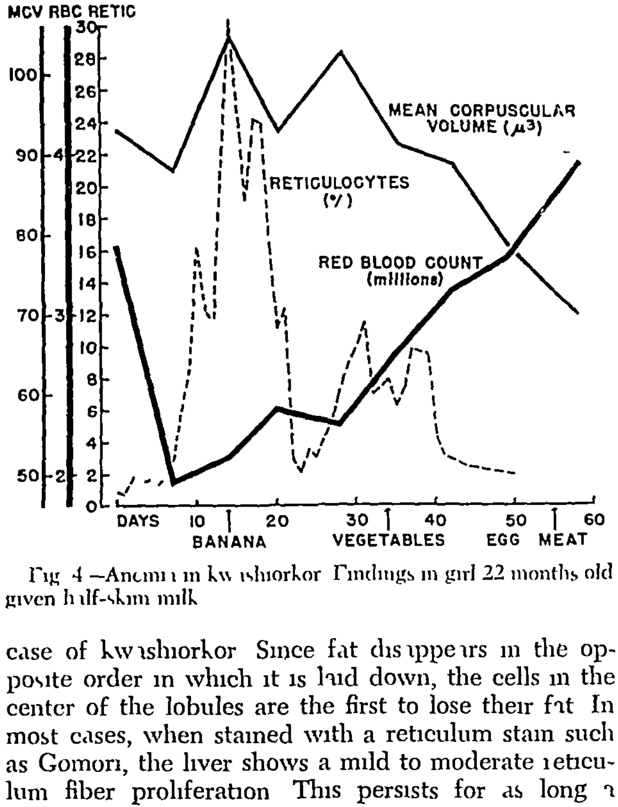

Fig 4—Anemia in kwashiorkor Findings in girl 22 months old given half-skim milk

Associated with this reticulum fiber proliferation is an increase in the number of histiocytes in the portal spaces In some cases a thickening of the walls of the central veins that stains for reticulum and sometimes for collagen is noted The thickening is different in type from that described by Bras[9] under the name of veno-occlusive disease In none of our cases has a true hepatic cirrhosis been found The possible relationship of the reticulum fiber proliferation to fibrosis in the adult is unknown

Biochemical Recovery—Changes in levels of certain biochemical substances occur during recovery

Serum Protein The prompt response in most cases of kwashiorkor to a diet rich in protein is illustrated for one individual case in figure 1 The average increase in serum protein and albumin levels with adequate treatment is shown in figure 7 A rise in serum albumin from 1 7 to 3 1% and in total serum protein from 3 8 to 6 3% in only two weeks illustrates well the rapid recovery that can take place

Serum Vitamin Changes As might be expected, changes in some of the serum vitamin levels are profound Figure 8 shows the very low levels of vitamin A found in patients upon admission and the gradual rise that occurred as treatment proceeded This rise was greater when 5 000 units of vitamin A were given daily for the first two to three weeks in addition to the 800 to 900 units contained in the daily diet The oral administration of a single dose of 75 mg of vitamin A produced no effect on serum vitamin A levels in children admitted with kwashiorkor [2a] However, only five days after milk therapy was begun, this oral dose produced a prompt and significant increase in the serum levels of vitamin A The serum carotene and vitamin E levels, also initially low, rose with treatment

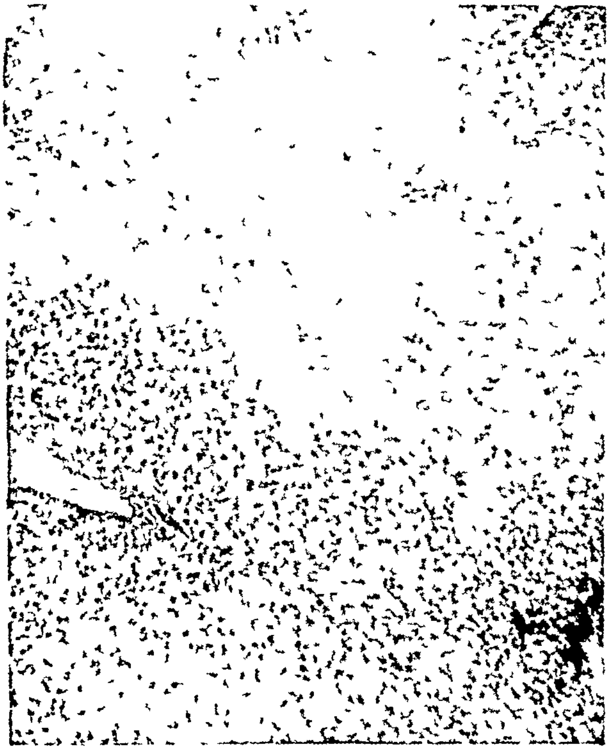

Fig 5 —Microscopic appearance of liver in boy 3 years of age with acute kwashiorkor after five days of dietary treatment This section shows disappearance of fat droplets in cells of central portion of lobules On patient's admission all of liver cells appeared to contain fat (hematoxylin and eosin stain)

In general, we have not found the amount of water-soluble vitamins to be greatly lowered in serum The data summarized in figure 9 show a rise with treatment in the values for both total riboflavin and the so-called free riboflavin fraction We find that ascorbic acid values also rise with treatment

Serum and Tissue Enzymes The rapid rise in the activity of serum enzymes with the feeding of good quality protein is striking Figure 10 illustrates the increase in serum amylase level that takes place with treatment Esterase and lipase show similar responses [3a] All three enzymes have their principal origin in the pancreas and therefore are useful indicators of the altered pancreatic function in the syndrome and of the recovery in response to treatment

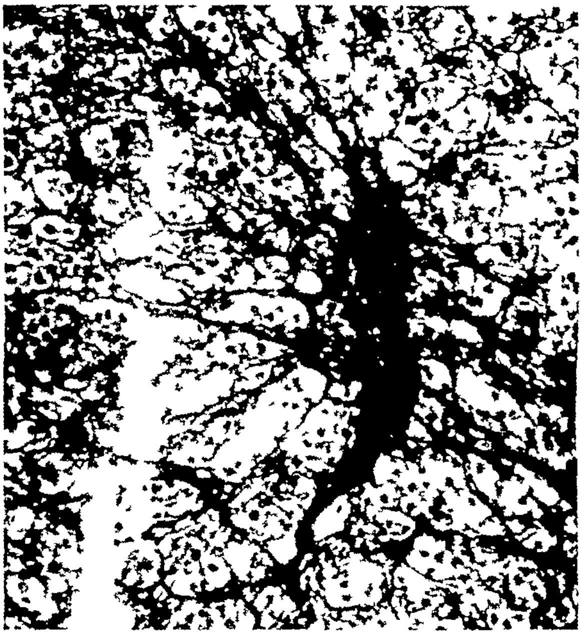

Fig 6 —Microscopic appearance of liver in boy 5 years of age admitted to hospital with acute kwashiorkor and given four weeks of dietary treatment This section shows extensive reticulum fiber proliferation commonly seen after clinical recovery (Gomori stain)

Figure 10 also shows the rise in levels of alkaline phosphatase and pseudocholinesterase (a nonspecific enzyme that hydrolyzes not only esters of choline but a variety of noncholine esters as well) We have found the latter to be the most sensitive indication of satisfactory response After an initial drop, alkaline phosphatase level shows a similar rise with treatment [2a]

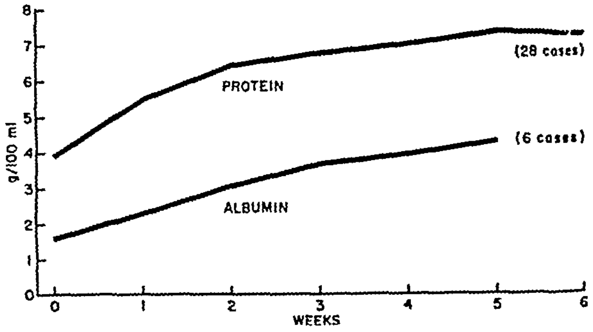

Fig 7 —Response of serum protein and albumin levels to diet therapy in kwashiorkor

Just as this syndrome of protein malnutrition is associated with a widespread decrease in the activity of other enzymes, so is there an equally widespread and rapid recovery Waterlow[10] has shown, through a study of liver biopsy specimens from malnourished children in Gambia, British West Africa, that the pseudocholinesterase activity increases more than 100% when a milk diet is given Although cytochrome oxidase and lactic dehydrogenase levels are not affected, the level of transaminase in the liver also rises[10] The alkaline phosphatase activity of liver biopsy tissue increases in kwashiorkor and decreases with treatment The duodenal amylase, lipase, and trypsin levels rapidly return to normal in the first 10 days of treatment[2a]

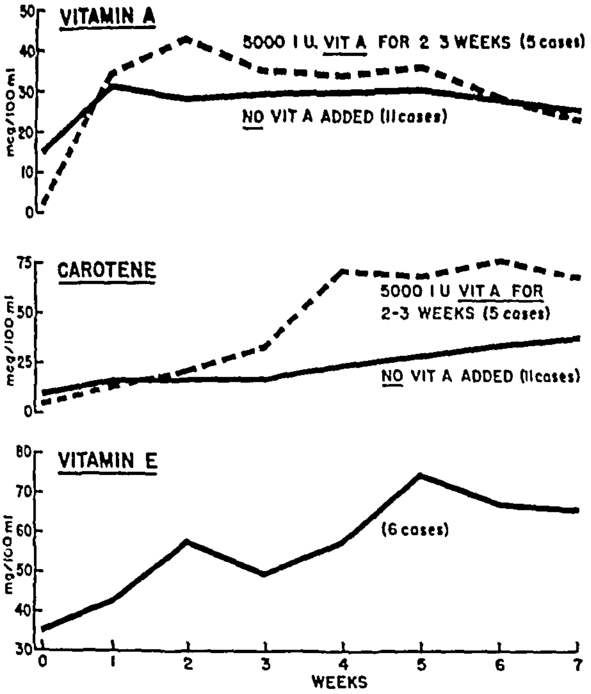

Fig 8 —Response of serum carotene and vitamins A and E levels to diet therapy in kwashiorkor

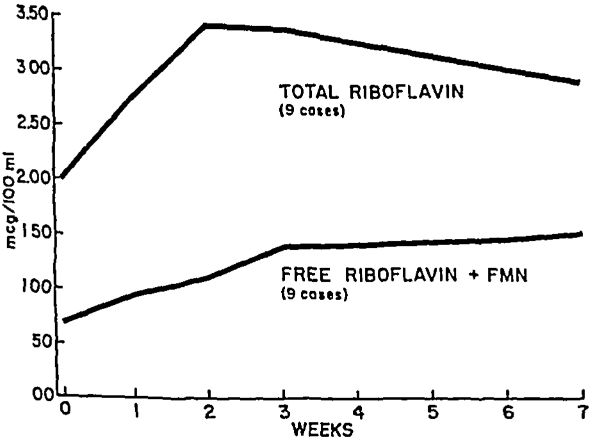

Fig 9 —Response of serum riboflavin level to diet therapy in kwashiorkor

Other Biochemical Changes Serum cholesterol values rise rapidly with treatment,[11] and the ratio of free to total cholesterol falls rapidly in the first two weeks The low-average serum blood urea levels rise to values that exceed the normal level[10]

Physiological Changes—It has already been mentioned that nitrogen balance is strongly positive in the early phases of recovery and nitrogen retention is high In the four children we studied for such data, we found that retentions range between 14 0 and 52 9% even relatively late in recovery When the child reaches normal weight for height, however, the retention of nitrogen drops sharply regardless of the amount absorbed The percentage of dietary fat retained decreases in the acute phase of the protein deficiency but rises with treatment[7a] In our own studies fat retention is variable but does not return to normal even late in the recovery period[1] The electrocardiographic changes of the acute phase referred to before also disappear early in recovery[8] We have recently noted that, when a patient is admitted, the size of his heart is decreased relative to the size of his chest, the heart increases in size with treatment (fig 11)

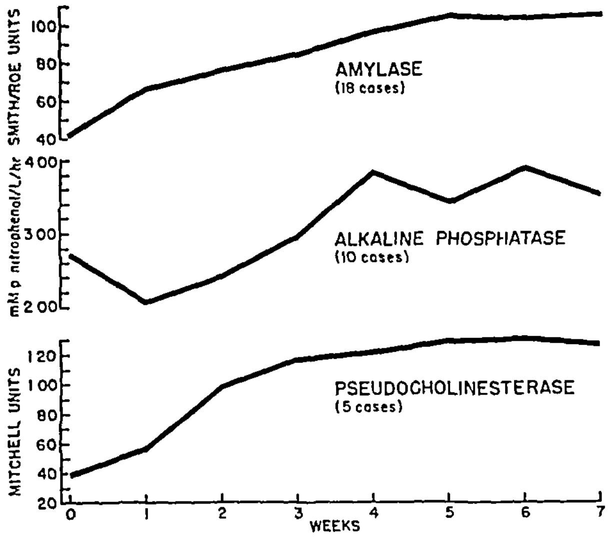

Fig 10 —Response of three serum enzyme levels to diet therapy in kwashiorkor

A curious set of findings is occasionally encountered relatively late in recovery These findings were originally described by Gomez and his group in Mexico under the name of the 'recovery syndrome'[12] The liver increases in size, and collateral circulation often is plainly evident, suggesting cirrhosis An increase in eosinophil count is observed, and hypertrichosis also may develop It has been suggested that this syndrome is caused by a recovery of pituitary function prior to the recovery of other endocrine organs, with a resulting imbalance We have occasionally seen this in mild form in Central America, and scattered cases have been reported from other parts of the world We suspect that this recovery syndrome is aggravated by a high caloric intake with a relatively low proportion of protein

Relation to Caloric Deficiency

A discussion of protein malnutrition would not be complete without pointing out that it is usually associated with a recent or long-standing deficiency of calories The cases in which there is a loss of subcutaneous fat and muscular wasting, initially obscured by the edema, are spoken of as the marasmic type of kwashiorkor because they combine degrees of both marasmus or starvation and protein deficiency In general, these cases are clinically more severe and require longer hospitalization Since most of the cases of kwashiorkor occurring in Mexico, Central and South America, India, South Africa, and the Belgian Congo are of this type, it is sometimes difficult to separate the effects of protein and calorie deficiency However, in Jamaica and Uganda, where children may develop kwashiorkor without the loss of subcutaneous fat and muscular wasting, and despite the consumption of an abundance of calories, the changes that have been described as characteristic of kwashiorkor also occur

Comment

A relative deficiency of protein of high biological value is the outstanding common finding in the diets of children in whom kwashiorkor develops Furthermore, the principal characteristics of this disease disappear promptly when skim milk alone is given It is given initially in a dilute form to provide a relatively low level of protein until it is easily tolerated by the patient The concentration of milk is gradually increased until 4 to 8 Gm of protein per kilogram of body weight is given by the fifth day, followed by gradual addition of other foods to supply a balanced diet rich in protein Parenteral therapy is usually unnecessary

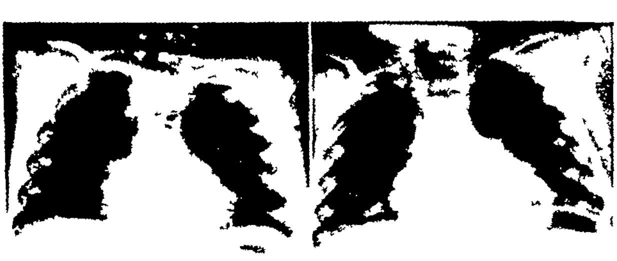

Fig 11 —Anterior posterior roentgenogram of thorax in boy 2 years, 7 months of age upon admission (*left*) and with initial recovery well advanced after 14 days of dietary therapy (*right*) Photographs indicate an increase in relative size of heart with treatment

These observations form the basis for considering kwashiorkor to be primarily a manifestation of severe protein deficiency Further support has been given to this concept by the work of Brock and others,[13b] who have demonstrated that vitamin-free casein alone will bring about an "initiation of cure" including disappearance or improvement of all of the major signs and symptoms A mixture of 18 amino acids, as in casein, with the addition of glucose, a mineral mixture, and all known vitamins was also effective Removal of the vitamins did not seriously affect the rate of initiation of cure Hansen and co-workers[13b] have also reported satisfactory initiation of cure with a mixture containing the 10 essential amino acids plus tyrosine, minerals, vitamins, and glucose When the vitamins were omitted from this mixture, the rate of initiation of cure was distinctly retarded

A remarkable thing about kwashiorkor is the dramatic rapidity with which it usually responds to a diet rich in protein It would be suspected, a priori, that children with atrophied gastrointestinal walls, whose duodenal enzyme activity is reduced to negligible levels, would be unable to use large quantities of protein at the time of admission to the hospital with acute kwashiorkor Nevertheless, the response to protein administration is so rapid that a few days later enzyme activities have returned to normal[14] and the absorption and retention of protein given in relatively large quantities is high[15] The response of serum vitamin A levels to vitamin A administered orally, on admission and after four days of treatment, indicates that the ability of the child to absorb fat-soluble vitamins shows a similarly rapid recovery[23]

Our own experience in Central America and that of workers in other parts of the world demonstrates conclusively that the preferred treatment of kwashiorkor is not the parenteral administration of protein hydrolysates, vitamins, or other medical preparations but rather the oral administration, by stomach tube if necessary, of adequate quantities of milk or other sources of protein of good quality There is reason to believe, from our work and that done in Coonoor, South India, and in Kampala, Uganda, that suitable vegetable protein mixtures are also satisfactory for this purpose[16]

Occasionally, whole blood transfusion may be deemed necessary to save the life of the child, but it is our experience that, as confidence in simple feeding is gained, the decision to resort to blood transfusion is rarely made Hansen and Brock[4] have emphasized the importance of fluid and electrolyte depletion, particularly of potassium, in diarrheic children with kwashiorkor They recommend routine oral administration of an electrolyte solution containing potassium (Darrow's solution) with glucose for the first 24 hours, before starting to feed protein

The prevention of kwashiorkor must be a goal of public health services and international health agencies, but the detailed study of the characteristics of the syndrome and its response to protein therapy has been enormously helpful in emphasizing the need for prophylaxis This advancement should also serve to lessen the initial cost of hospital treatment of the condition, by eliminating costly parenteral therapy from the procedures routinely employed, and to shorten the hospital stay, by protecting the malnourished child from the cross infections of the general pediatric ward

Summary

The characteristics of severe protein malnutrition (kwashiorkor) in children include retarded growth and development edema anorexia, apathy and sometimes irritability, hair and nail changes, skin lesions diarrhea, anemia lowered serum protein and *albumin* lowered serum levels and absorption of fat soluble vitamins, lowered serum levels of pseudocholinesterase, amylase, lipase and alkaline phosphatase reduced duodenal enzyme activity, fatty liver, reduced heart size, and lowered electrocardiographic voltages All of these return to normal or improve greatly within the first 7 to 10 days of protein therapy, apparently even when this therapy is given in the form of vitamin-free casein Suitable vegetable protein mixtures may also be used

Children exposed to cross infection in open pediatric wards require longer hospitalization for satisfactory recovery The associated deficiency of other nutrients can be corrected by diet alone except when severe iron deficiency caused by malaria or hookworm is present, in that case, supplementary iron should be given orally There is no convincing evidence that vitamin B_{12}, lipotropic substances, or enzyme preparations have a place in the treatment of kwashiorkor

This investigation was supported in part by a research grant from the National Institute of Arthritis and Metabolic Diseases, Public Health Service, and by funds from the Nutrition Foundation Inc the Williams Waterman Fund of the Research Corporation and the World Health Organization This paper is INCAP Scientific Publication I-65

High Altitude Polycythemia —Studies of high-altitude polycythemia have been carried out largely in the Peruvian Andes, where many people live at altitudes of more than 12,000 feet When normal persons move to high altitudes, they undergo a period of acclimatization marked by an initial hemoconcentration, with increased values for hemoglobin and the cell-volume per cent (hematocrit) and an increase in the number of erythrocytes, there is no immediate increase in the total erythrocytic mass, although this does occur some days later Rates of turnover of plasma iron, however, increase greatly in the first 12 hours at high altitudes This occurs more quickly than can be observed in studies of the peripheral blood and bone marrow Reticulocyte counts reach a peak in about a week Natives living at high altitudes show increased total erythrocytic masses, with normal plasma volumes The rates of turnover of plasma iron are not so high as those of persons recently arrived in the region On descent from high altitudes, a pronounced decrease occurs in the rate of erythropoiesis (as indicated by decrease in the turnover of plasma radioiron), the rate often decreasing to values less than normal Splenomegaly is uncommon in natives living at high altitudes, and the leukocyte and platelet counts are not increased —C F Stroebel, M D , and W S Fowler, M D , Secondary Polycythemia, *The Medical Clinics of North America,* July, 1956

NEW PROBLEMS FOR PHYSICIANS

Elsewhere in this issue of THE JOURNAL (page 566) is a report on some aspects of the Old-Age and Survivors Insurance disability program The American Medical Association has opposed consistently amendments to the Social Security Act leading to such a program Physicians throughout the country have been warned of the problems that inevitably will arise because of this program However, in spite of these and other warnings, the program is now covered by law, and many physicians and many patients will increasingly be made aware of it as medical reports are prepared for the Bureau of Old-Age and Survivors Insurance

The report appearing elsewhere in THE JOURNAL is intended to supply physicians with information on what the program entails It was prepared under the direction of a special committee of the Board of Trustees of the American Medical Association, the Committee on Medical Rating of Physical Impairment One aspect of the program which must be understood, ven though it may not be acceptable to many, is the ole of the physician as he assists his patient applicant e merely assists in providing the administrative agen y with a written report of clinical findings and medi facts The administrative agency will determine er the applicant s condition qualifies him medi as disabled under the program

Other points of special interest include

The term permanent and total disability does not ppear in the statutory definition of disability So while this program is popularly referred to as a permanent and total disability program, such reference s not an accurate one

An individual is not necessarily eligible under this rogram even though he may be considered 'perma entlv totally disabled' under another private or pub ic program

The degree of participation by the medical profes ion in the selection of medical personnel and the levelopment of medical policies and practices of the state administrative agency depends on the relationship between the agency and the medical profession at the state level

It is the applicant s responsibility to obtain, at his own expense, sufficient medical evidence to prove his disability

Consultative examinations at government expense may be authorized to verify the medical evidence submitted by the applicant or to provide additional medical data needed to confirm the diagnosis or severity of the applicant's present condition

The applicant s attending or examining physician may be authorized by the state agency to develop, at government expense, this additional medical data needed to confirm the diagnosis or severity of the applicant's present condition

An administrative agency may adopt a policy that the physician making the consultative examination must be mutually acceptable to both the applicant s attending or examining physician and the medical personnel of the administrative agency authorizing the consultative examination

The Committee on Medical Rating of Physical Impairment was appointed as an *ad hoc* committee of the Board of Trustees on September 14, 1956 Committee members are James R McVay, Chairman, Kansas City, Mo , George F Gsell, Wichita, Kan , Henry H Kessler, Newark, N J , Quentin W Mack, Boise, Idaho, and O A Sander, Milwaukee

The committee s objectives are as follows

To establish guides for medical rating of physical impairment, and lists by body systems of permanent impairments and their relation to permanent total disability

To provide liaison between the American Medical Association and the Bureau of Old-Age and Survivors Insurance on medical aspects of its program for the disabled

To study such other programs for the disabled as the committee may find of value in performing its duties

To inform constituent medical associations of current activities of the committee

The committee has met several times With the assistance of consultants, it has begun its work But it will need the understanding of the medical profession as this program develops Without such understanding, problems for the patients and their doctors will be made more acute

TOLBUTAMIDE FOR DIABETES MELLITUS

The release of the orally given hypoglycemic agent tolbutamide (Orinase) for prescription use in the management of selected cases of patients with diabetes mellitus imposes new responsibilities on the physician While tolbutamide may make unnecessary the routine use of insulin in many such patients, it is mandatory that the physician acquaint himself with the details of selection of patients and their management with this drug In patients with a satisfactory response to tolbutamide, the blood sugar level falls, glycosuria diminishes, and such symptoms as pruritus, polyuria, and polyphagia disappear, however failure to observe recommended precautions can cause deterioration of the patient's state of health and well-being

This drug is a member of the sulfonamide family and carries with it a risk for some patients, even though apparently slight because of its chemical structure The real and more serious problem, however will arise if the drug is dispensed without a prescription for self medication or if it is used in patients for whom it obviously is not indicated Tolbutamide is not a substitute for insulin and must not be used in the juvenile type of diabetes Such insulin-dependent diabetics must depend on hormonal replacement therapy in addition to careful dietary regulation Tolbutamide is of no value in diabetes complicated by acidosis and coma, here insulin is indispensable

Any physician using tolbutamide should insist that during the initial test period the patient report to the physician daily and for the first month report at least once weekly for physical examination, blood sugar level determinations, and white blood cell count After the first month the patient should be seen at least once a month and the above studies carried out

For the protection of both patient and physician, uncooperative patients should not be considered suitable for treatment with tolbutamide Since not all patients with diabetes mellitus are suitable candidates for therapy with this drug, it is essential that the physician know the limits of application and the criteria for selecting patients for treatment with it It is especially important for the patient not to develop a careless attitude, because it will result in serious health consequences and failure of treatment The use of tolbutamide gives no diabetic license to ignore dietary restrictions, and all of the usual diagnostic and therapeutic measures necessary to insure optimal control of the diabetic state with insulin are equally necessary for control with this drug

The following precautions must be observed 1 The patient on tolbutamide therapy must receive full and complete instructions concerning the nature of his disease and what he must do to prevent and detect complications and to control his condition 2 He must fully understand that he cannot disregard instructions relative to body weight, exercise, personal hygiene, and avoidance of infections 3 He must be informed about how and when to test for glycosuria and ketonuria and how to recognize and counteract impending hypoglycemia 4 He must be informed that treatment only controls rather than cures diabetes and that, for good control to be maintained, directions regarding diet and dosage of the drug must be followed rigidly 5 Care must be exercised to avoid ketosis, acidosis, and coma, especially during the trial period when insulin is being withdrawn

Use of tolbutamide is contraindicated in patients having (1) juvenile or growth-onset type diabetes mellitus, (2) unstable or "brittle" type diabetes mellitus, (3) history of diabetic coma, (4) maturity onset diabetes complicated by severe ketosis, acidosis, diabetic coma, severe trauma, gangrene, Raynaud's disease, or serious impairment of renal or thyroid function, (5) hepatic dysfunction or (6) diabetes mellitus adequately controlled by dietary restriction

The diabetic patient whose condition is most likely to be tolbutamide-responsive is one in whom the disease is relatively mild and stable and developed some time after the age of 30 years Responsiveness is measured by a satisfactory reduction in blood sugar level and glycosuria during the trial period, which should be continued for five to seven days provided ketosis does not intervene The patient is considered nonresponsive to tolbutamide if any of the following conditions develop ketonuria, glycosuria, unsatisfactory decrease in or persistent hyperglycemia, serious side-reactions, or failure to obtain subjective or objective clinical improvement

The recommended dosage for tolbutamide therapy in a suitable candidate, whether he is or is not receiving insulin, is as follows on the first day, 3 Gm , on the second day, 2 Gm , on the third day, 1 Gm On occasion, depending on the clinical response, dosage is decreased more slowly, but this period should not exceed one week Thereafter, the daily dose, which can be given as a single dose each morning or in divided doses, is adjusted as required to obtain optimal control The ultimate maintenance dose may be as little as 0 5 Gm daily or as much as 1 5 Gm daily The usual maintenance dose is 1 Gm Maintenance dosage over 2 Gm should be avoided

When patients receiving insulin are converted to tolbutamide therapy, insulin should be withdrawn slowly and its administration not stopped abruptly During the withdrawal period the patient should test his urine for sugar and ketone bodies as often as three times daily and report the results to his physician daily Patients whose insulin requirement is less than 40 units daily may be started on tolbutamide therapy with a concurrent 30 to 50% reduction in insulin dose, with further daily reduction of the insulin as response to tolbutamide is observed In patients requiring more than 40 units of insulin daily, tolbutamide therapy may be initiated in conjunction with a 20% reduction in insulin dose the first day, with further careful withdrawal of insulin as response to tolbutamide is observed The too rapid conversion from insulin to tolbutamide may result in aggravation of the diabetic state and ketosis, even in those patients whose insulin requirement is small During the conversion period, hypoglycemic reactions may occur, these are readily controlled by the administration of glucose or by modification of the dose

Combination tolbutamide-insulin therapy is rarely useful or necessary, and it is not recommended All patients who develop ketosis or serious side-effects other than hypoglycemia or in whom unsatisfactory blood or urine sugar level control results should have tolbutamide withdrawn and be returned to their former insulin therapy

During the course of intercurrent complications, such as ketoacidosis, severe trauma, major surgery, infection, severe diarrhea, and vomiting, supportive insulin therapy becomes mandatory Depending on the severity of the diabetes, the nature of the complications, and the availability of laboratory facilities tolbutamide therapy may be continued or may be withdrawn while insulin is being used However, if tolbutamide is not withdrawn, extra care must be exercised to avoid hypoglycemic reactions Because insulin is indispensable for the management of complications, all patients receiving tolbutamide should be carefully instructed in the proper use of insulin

The use of members of the sulfonamide family for their hypoglycemic effect has been studied for some years One agent is now sold in Canada, and the drug can be obtained in other countries In the United States at least two have been studied extensively One has been withdrawn even for experimental use, the other, tolbutamide, is now available since the Food and Drug Administration has made effective a new drug application Much work has been undertaken as this substance has been studied More, however, remains For example, what may happen when the drug is administered for many years remains to be seen In the meantime, physicians must warn their patients that this drug is not a true substitute for insulin but in carefully selected patients can be used instead of insulin to control the blood sugar level If the patients are not warned properly, if they do not cooperate, or if the prescribers of the drug do not understand its limitations, trouble will inevitably arise

NATIONWIDE NATIONAL HEALTH SURVEY BEGINS

The National Health Survey program has progressed to the point that field work on household interviewing began, nationwide, on May 6 The survey represents the first effort in 20 years to obtain comprehensive statistics on illness in the general population

The Public Health Service is undertaking the survey ontinuing basis pursuant to legislation enacted session of the Congress There has, of course, creasing recognition for some time of the fact , for the general population, information on health conditions is seriously out of date An important step toward remedying this situation was the establishment in January, 1949, of the U S National Committee on Vital and Health Statistics Two successive *ad hoc* subcommittees were set up by the chairman of the national committee "to frame the problems in morbidity statistics, including chronic diseases and medical care statistics, in order that morbidity data may be directly related to demographic factors' These subcommittees recommended the study of a number of methodological questions, and in several community surveys a start was made in the investigation of some of these questions A third *ad hoc* subcommittee was created in 1951 and charged with the task of drafting 'a plan for a national morbidity survey keeping in view the interests of local areas' The report of this subcommittee, "Proposal for Collection of Data on Illness and Impairments United States,'[1] became the basis for the new National Health Survey law (P L 652, 84th Congress)

The legislation was sponsored by the administration and enjoyed bipartisan endorsement The American Medical Association supported it, while cautioning that any survey in this area should be conducted in such a manner that all interested parties can agree substantially with its conclusions The House Committee on Interstate and Foreign Commerce embraced this caution, repeating it in its report on the measure

Operation of the survey is centered in the Public Health Service's division of public health methods Dr Forrest E Linder, formerly of the National Office of Vital Statistics and more recently chief of the demographic and social statistics branch of the United Nations Statistical Office, has returned to the PHS as the survey director Dr Alice M Waterhouse is staff medical advisor The survey program will have the benefit of a national advisory committee composed of representatives of medicine, dentistry, hospital administration, biostatics, labor, insurance agencies, pharmaceutical houses, and other interested disciplines and groups The American Medical Association will be represented on this committee by Dr Henry B Mulholland of the Council on Medical Service, with Mr George W Cooley of the Council staff serving in a staff capacity to Dr Mulholland

The survey program will consist of three parts a continuous sampling of households on a national basis, information being collected in each household by carefully trained and supervised lay interviewers, a series of special studies to gather information of a type for which a household interview method is not appropriate, and a series of methodological studies designed to improve the techniques of measurement of illness and to check the validity of data collected in the interview survey and special studies

The household interview is the first of these parts to get under way on a full scale The field work for this part of the study will be conducted for the public Health Service by the Bureau of the Census At the beginning, the interviewing will be done in 330 Census Bureau primary sampling units, which consist of counties, parts of counties, combinations of counties, or metropolitan areas chosen to produce a representative sample of the population There is at least one sampling unit in each state, and in most states there are several Within these areas, repeated samples of households will be drawn for interviewing Since a one-time interview is planned, subsequent samples will consist of different households each month Also, since the size of the national sample is small—3,000 households per month—the number of households interviewed in any one area will be small

---

[1] Proposal for Collection of Data on Illness and Impairments United States, PHS Publication 333, Department of Health Education, and Welfare, Public Health Service, Oct, 1953

The interview questionnaire includes questions about illnesses of all kinds and whether they are medically attended, chronic conditions and impairments whether or not they interfered with the person's usual activities, dental conditions and dental care, disability and, separately, bed disability, symptoms, accidents and injuries, and hospitalization

The present plan is to compile periodically separate morbidity statistics for the country as a whole and for each of 11 geographical regions of the country Data from these regions will be shown separately for large metropolitan areas as a group, all other urban areas as a group, and rural areas In addition, statistics will be compiled separately for each of nine large standard metropolitan areas

MENTAL ILLNESS IS A MEDICAL PROBLEM

" [and] it is high time the medical profession launched a concerted attack on this problem' This emphasis was made recently by David B Allman, MD, President-elect of the American Medical Association, at a meeting of the 1957 National Health Forum on 'Better Mental Health—A Challenge to All Health Services"

"As a physician,' Dr Allman stated in his speech, "I am concerned about the responsibilities of the medical profession in treating mental patients—and more important in preventing further increases in mental illness in the future

Decades ago, mental illness was considered a social, moral, and legal problem, with mentally disturbed people treated as witches, possessors of evil spirits, or objects of public hilarity Today, the conscientious, well informed doctor, realizing that even physical illness can be mentally induced, puts more emphasis on treating the whole person to solve his mental as well as physical problems

Dr Allman pointed out that only about 4% of the practicing physicians in this country are psychiatrists Great as their contributions are, these few men cannot do the job alone What is the medical answer? It is obvious that every doctor, no matter what his specialty, must accept a greater share of responsibility for aiding in the solution of these problems

The psychiatrist needs the intelligent cooperation of other doctors in every type of practice Who is in a better position to deal with mental health and potential mental illness than the doctor who has maintained a close relationship with his patients over a long period of time? Unfortunately, not all who could be helpful have realized their responsibilities in this area It has taken a long time to accept the idea that present-day psychiatry is of interest to the entire realm of medicine

Dr Allman listed what he believed to be the physician's responsibilities in regard to mental illness

First, a physician must know his patients

Second, a physician must recognize and accept the value of psychiatric techniques in dealing with all his patients

Third, a physician must be acquainted with all the community services and resources available in treating and rehabilitating the mentally ill

Fourth, a physician should integrate the whole treatment and rehabilitation process He can help the patient's family understand the nature of the illness and show them how they can best help the patient during his treatment He can act as a mediator when the patient is released and must be rehabilitated

Fifth, a physician has a tremendous educational job to do, not only with patients and patients' families but with the general public in regard to mental illness and mental health

Elaborating on Dr Allman's last point, attention is directed to the fact that throughout the country, during the month of May, the National Association for Mental Health and its 500 affiliates, in cooperation with the National Institute for Mental Health, are conducting a drive to arouse public interest in the fight against mental illness Every physician has an important role to play in these observations As a scientist and physician he can help to educate the public with regard to mental illness As a citizen in his community he can work with the local mental health association to help heighten public awareness so that the task of combating mental illness will not be left to the medical profession alone, but rather to all the people of the United States

REGISTRATION UNDER THE HARRISON NARCOTIC ACT

Physicians who are registered under the Harrison Narcotic Act or under the Marihuana Tax Act must effect reregistration on or before July 1 to avoid penalty Each year, despite the annual warnings in The Journal, this requirement is overlooked by some physicians, and unpleasant consequences follow Failure to register adds a penalty of up to 25% to the tax payable and, in addition, subjects the physician who continues to dispense to the possibility of a fine not exceeding $2,000 or imprisonment for a maximum of five years, or both The Commissioner of Internal Revenue has in past years given some tardy registrants the choice of paying sums by way of compromise, a procedure authorized by law, or accepting criminal prosecution If this procedure does not produce the required promptness in reregistration, the commissioner will have no choice but to institute criminal prosecution

This requirement for registration and reregistration does not apply to the physician who does not intend to prescribe or use narcotics in his practice or to possess narcotics

ORGANIZATION SECTION

OLD-AGE AND SURVIVORS INSURANCE DISABILITY PROGRAM

The Committee on Medical Rating of Physical Impairment of the Board of Trustees has been assigned as one of its tasks the review and study of developments under the disability program administered by the Bureau of Old-Age and Survivors Insurance The information in the following pages relating to various aspects of this program has been obtained from reviewing the present law and statements of administrative policy and procedure issued by the Bureau of Old-Age and Survivors Insurance as well as from conferences with representatives of the bureau's staff and with members of its medical advisory committee—Ed

Introduction

The primary purpose of this report by the Board of Trustees Committee on Medical Rating of Physical Impairment is to inform the medical profession on certain aspects of the disability provisions in the Old-Age and Survivors Insurance (OASI) section of the Social Security Act Although the American Medical Association has consistently opposed amendments to the Social Security Act leading to such a program for the disabled, the proposal is now law Most physicians will be requested by patients from time to time to submit medical reports to the Bureau of Old-Age and Survivors Insurance (BOASI) It is, therefore, desirable for all physicians to be familiar with the information contained in this report and especially with the following points

1 The role of the physician in this program is to assist the patient-applicant in providing the administrative agency with a written report of clinical findings and medical facts on the basis of which the administrative agency will determine whether the applicant's condition medically qualifies him as disabled under the program

2 Disability is defined under this program as inability "to engage in any substantial gainful activity by reason of any medically determinable physical or mental impairment which can be expected to result in death or to be of long-continued and indefinite duration " From this definition it may readily be seen that disability *is not solely a medical question*

3 Determinations of disability involve consideration of both medical and nonmedical factors Such determinations are the sole responsibility of the administrative agency Attending or examining physicians are not expected by law or administrative regulation to express their opinions as to whether an applicant is or is not disabled as defined in the law

4 The BOASI establishes general policies and procedures under this program, and through its district office accepts applications and undertakes preliminary case development State administrative agencies have considerable latitude in implementing the medical aspects of the program in accordance with locally accepted practices

5 Misunderstandings between physicians and applicants can be avoided if physicians clearly explain their role to applicants and the scope and purpose of medical reports The fact should be emphasized that such reports represent only one factor in the administrative agency's decision as to whether or not an applicant is eligible for benefits under the program Applicants should be referred to BOASI district offices for information on such matters as eligibility requirements and amount of monthly benefits The location of these offices can be ascertained from any local post office

Program Provisions

1 *When are applicants required to submit medical evidence under the Old-Age and Survivors Insurance program?*

An applicant must furnish medical evidence when applying for

a Disability freeze, under which a qualified individual may protect himself and his family against loss of future benefits by having his Social Security account "frozen "

b Disability insurance benefits, under which a qualified individual age 50 or over may receive monthly payments beginning July, 1957 The amount of the payments will be determined as though the applicant had reached 65 on the date he became disabled

c Disabled child's benefits, under which dependent sons or daughters of retired or deceased qualified individuals, or the mother who has in her care such disabled son or daughter, may receive monthly payments beginning January, 1957 These payments are made in cases where disability began before age 18, regardless of present age

2 *When is an individual considered disabled under the Old-Age and Survivors Insurance disability program?*

An individual is "disabled' or 'under a disability' when he is unable to engage in any substantial gainful activity by reason of any medically determinable physical or mental impairment which can be expected to result in death or to be of long-continued and indefinite duration It should be noted that the terms permanent and total' do not appear in the definition of disability So while this program is popularly referred to as a "permanent and total disability program, such reference is not an accurate one

3 *What constitutes "substantial gainful activity"?*

Services of a substantial nature performed in competitive employment or self-employment with reasonable regularity may be considered to constitute substantial gainful activity However, there is no specific dollar measure for determining 'substantial gainful activity ' Careful consideration must be given to all the facts in each case the hours worked, the nature of the services, the continuity and duration of the period of services, etc

4 *What is meant by a 'medically determinable" impairment?*

The committee members are James R McVay Chairman Kansas City Mo, George F Gsell Wichita, Kan, Henry H Kessler Newark, N J Quentin W Mack, Boise, Idaho and O A Sander Milwaukee

This means that the impairment must be one that can be determined by a physician on the basis of examinations or tests

5 *What is meant by "long-continued and indefinite duration"?*

This means that no approximate date of recovery or improvement can be predicted with reasonable assurance

6 *What is an "impairment"?*

An 'impairment" is a physical or mental disease, anatomic abnormality or loss, or combination of these An impairment must be so severe as to justify its consideration as the cause of failure to obtain any substantial work

7 *When is 'blindness' considered a disability?*

Blindness per se is considered a disability for freeze" purposes only Blindness" for this purpose is defined in the law as central visual acuity of 5/200 or less in the better eye with the use of a correcting lens An eye in which the visual field is reduced to five degrees or less concentric contraction shall be considered for the purpose of this paragraph as having a central visual acuity of 5/200 or less " To be eligible for monthly payments even a totally blind person must establish that he is unable to engage in any substantial gainful activity However, a person who has a less severe visual impairment may also be eligible for the freeze or monthly insurance benefits if his impairment prevents him from engaging in any substantial gainful activity

8 *When would a claim for disability be denied in spite of a severe impairment?*

A finding of disability may not be made when an individual can do or is doing substantial work despite the impairment, as where he has special vocational skills or experience, or if the impairment is amenable to safe and acceptable treatment

Requirements for Eligibility

9 *What requirements must an applicant meet to be eligible under the freeze or monthly payments provisions of the OASI disability program?*

To qualify for monthly payments or to have his Social Security record frozen, an individual must

a Have Social Security credit for at least 5 years' work in the 10 years before the beginning of his disability, and

b Have a work record in covered employment for at least 1½ years during the 3 years just before he became disabled, and

c Have been disabled for 6 months or more at the time he files his application, and

d Produce medical evidence that he is disabled or under a disability as defined in the law

10 *What requirements must an applicant meet to be eligible for monthly payments under the disabled child's provision of the OASI disability program?*

To qualify for monthly payments, an individual must

a Have become disabled before reaching 18 years of age, and

b Be unmarried, and

c Be dependent upon a parent, step-parent, or adopting parent who is receiving Social Security old-age insurance benefits, or

d Have been dependent on a parent who died after 1939 and after working long enough under Social Security to become insured for the payment of survivors' insurance benefits, and

e Produce medical evidence that he is disabled or under a disability as defined in the law

To receive disabled child's insurance benefits, it is not necessary for such a person himself to have any record of work under Social Security An individual may also qualify at any age for these benefits provided he meets the requirements outlined above

11 *If an individual is receiving payments for 'total disability' under a private or another public program, will he be considered disabled under the OASI disability program?*

Not necessarily For example, his physical or mental impairment may not be serious enough or sufficiently prolonged to meet the definition of disability under this program Furthermore, he will not necessarily be considered disabled because he can no longer do the type of work required in his last job or any jobs he has held in the past, a characteristic frequently entitling an individual to benefits for total disability' under some other programs

12 *Under what circumstances other than cessation of disability may monthly payments, under the OASI disability program, be reduced, suspended, or delayed?*

Monthly payments will be reduced by the amount of any other cash benefits the disabled individual receives under a disability program of another federal agency except veterans' compensation based on service-connected disabilty, or under a state or federal workmen's compensation law Monthly payments may be suspended if the individual refuses without good cause to accept rehabilitation services available to him under a state plan approved under the Vocational Rehabilitation Act Policies and procedures in determining what constitutes good cause are being worked out by BOASI and state vocational rehabilitation agencies The actual determinations in specific cases will be made by BOASI Monthly payments are not payable for the first six months of disability, even though the individual may already be 50 years of age or older at the time his disability begins

Administration

13 *What agency administers the Old-Age and Survivors Insurance disability program?*

The responsible administrative agency is the Bureau of Old-Age and Survivors Insurance (BOASI) in the Department of Health, Education, and Welfare However, under an agreement between each state and the Secretary of the department, an agency in each state makes determinations of disability State agencies are reimbursed from federal funds for all necessary expenses In those cases not covered by state agreements the determinations of disability are made by BOASI

14 *What State agencies are designated to make determinations of disability?*

In 43 states the designated agency is the state vocational rehabilitation agency In New York, North Carolina, Washington, Oklahoma, and South Dakota, determinations of disability are made by the state public welfare agencies In 10 states, arrangements have been made for special agencies to make determinations where the principal impairment is visual Each state agency is expected to develop its own relationships with the medical profession in reference to medical consultants, medical advisory committees, consultative examinations, and other medical matters

15 *What medical aspects of the disability program are responsibilities of a state agency?*

A state agency s responsibilities include

a Evaluating the adequacy of medical evidence submitted by an applicant,

b Obtaining clarification of or additional medical evidence from the applicant or other sources,

c Authorizing and obtaining additional medical examination of the applicant, where necessary to verify medical evidence obtained by the applicant,

d Determining through the application of prescribed medical criteria whether the applicant is or is not under a disability,

e Recommending follow-up medical examinations, where indicated,

f Reconsidering disability determinations where requested by BOASI,

g Fostering mutual understanding with physicians in connection with administration of the program,

h Providing sufficient qualified personnel to evaluate pertinent medical data and other evidence, and to make determinations of disability in all cases covered by the agency's agreement with the department

16 *What administrative phases of the disability program are not responsibilities of the state agency?*

The State agency is not responsible for

a Determining whether the applicant has met the requirements of the law other than that he is or is not under a disability,

b Notifying the applicant of the determination in his case,

c Explaining the program to applicants,

d Conducting hearings on appeals from or defending agency determinations of disability

17 *What aspects of the disability program are responsibilities of a BOASI district office located in a state?*

The BOASI district office is responsible for

a Explaining the program to applicants and the public,

b Advising applicants regarding potential eligibility,

c Providing applications and other required forms,

d Assisting applicants in completing applications and obtaining necessary data from a physician, hospital, or other source,

e Accepting applications and requests for reconsideration or hearing,

f Forwarding case files for determination of disability to the appropriate state agency

18 *What administrative phases of the disability program are not responsiblities of the BOASI district office?*

The BOASI district office is not responsible for

a Making determinations of disability,

b Advising an applicant regarding the nature of his disability

19 *How do applicants file an application under the OASI disability program?*

Applicants may obtain and file the necessary forms and information at their local BOASI district office It is desirable for them to visit the office in person However, if they are unable to appear personally, they may write or telephone or have someone else do so for them The location of the appropriate office may be obtained from their local post office There are more than 550 such district offices

20 *What are 'determinations of disability'?*

Determinations of disability are the decisions that an applicant is or is not disabled, including the date of onset or cessation of disability

21 *How and by whom are determinations of disability made in a state agency?*

Determinations of disability are made by "review teams' in a state agency Each review team is composed of a disability examiner and a review physician

The reviewing physician (often a practicing physician) is responsible primarily for evaluating the applicant s medical evidence and assessing the severity of the impairment, or combination of impairments The disability examiner is the nonmedical member professionally qualified to assess the work history, occupational capacity, and other factors in the evaluation of a disabled individual's ability or inability to engage in substantial gainful activity

The determination of disability is the end-product of the application of these professional skills to the facts of each specific case and the assessment of the degree of physical or mental impairment along with the individual factors of age, education training, and employment experience All determinations of disability are made jointly and are signed by both members of the review team

In a few large state agencies, the reviewing physicians may be supervised by a medical consultant, although in other state agencies the medical consultant is also the reviewing physician A medical consultant's primary responsibility is to advise the state agency on broad policies relating to medical aspects of the program, recommending acceptable standards and procedures, and establishing liaison with medical and related professional groups Some state agencies have district medical consultants in addition to a state medical consultant A state agency may have more than one medical consultant

22 *Does the local medical profession participate in the selection of medical personnel and the development of medical policies and practices of the state agency in connection with the OASI disability program?*

The degree of participation by the medical profession depends upon the relationship between the state agency and the medical group The state agency is primarily responsible for the development and maintenance of a satisfactory relationship with the medical profession at the state level

23 *After the review team makes a determination of disability what happens?*

The file and recommendation of the state review team is sent to the division of disability operations, BOASI, in Baltimore, for review by medical and adjudicative personnel The BOASI may reverse the finding of a state review team that an applicant is disabled The BOASI may not, however, reverse a state finding that the applicant is not disabled However, in the latter case, the file may be returned to the state agency for reconsideration after which the state agency may affirm or reverse its original recommendation This does not mean that the state agency must reverse its decision, even when referred back for reconsideration the state agency can affirm or reverse its original recommendation as it sees fit

24 *How is the applicant notified of the decision on his claim?*

He receives a letter from BOASI When a claim is disallowed on the basis of medical evidence, no reference is made to the specific content of the medical reports contained in the file

25 *Can an applicant appeal from the decision of BOASI?*

Yes He may file a request with the BOASI district office for reconsideration or a hearing before a referee of the Social Security Administration Appeals from a decision by a referee may be taken to the U S District Court

26 *When and by whom are individuals referred for vocational rehabilitation services?*

Generally, the same review team which makes the determination of disability also decides whether the applicant should be considered for vocational rehabilitation services The names of any such individuals and any information in the file is used by the rehabilitation agency in its investigation and consideration of eligibilty for rehabilitation services

27 *Does BOASI have any control over vocational rehabilitation standards of eligibility established or services furnished by a state vocational rehabilitation agency involving applicants for disability benefits?*

No, these aspects are entirely in the hands of the state vocational rehabilitation agencies

28 *What follow-up is made in reference to rehabilitation?*

None by BOASI, the state vocational rehabilitation agency handles the case as it sees fit, reporting to BOASI when disposition of the case is made

29 *Do monthly payments under the disability program continue during the rehabilitation period?*

Yes Moreover, he may continue to receive benefits for as long as a year even though working, if his work is pursuant to a state plan approved under the Vocational Rehabilitation Act

Medical Evidence

30 *How are BOASI medical policies and practices established?*

BOASI medical policies and practices are established by consultation between its medical and lay administrators and its medical advisory committee These medical considerations serve as general guides for the state agencies when affecting determinations of disability

31 *What is the medical advisory committee and when was it appointed?*

In February, 1955, the commissioner of Social Security appointed a committee, representative of a wide variety of skills in medical practice and public and private medical and welfare administration and of the major geographical areas of the country, to advise him on medical policies involved in administering the disability freeze provision of the Social Security Act Subsequently the committee's duties were enlarged to include all provisions of the OASI disability program Since its appointment in 1955 the committee has met six times

32 *What are the purposes of the medical advisory committee?*

The purposes of the medical advisory committee are

a To provide technical advice and consultation regarding medical aspects of the administration of the disability program

b To promote mutual understanding and effective working relationships among the Social Security Administration, cooperating state agencies, and physicians generally

c To provide professional guidance in formulating medical guides and standards for evaluating disability

33 *What medical criteria are used by state and federal review teams in evaluating specific impairments and combinations of impairments?*

The Department of Health, Education, and Welfare has prepared guides for the review teams in federal and state agencies The guides contain descriptions of more than 130 commoner types of conditions that usually result in total disability They contain clinical descriptions of these conditions in terms of anatomic damage and functional loss that demonstrate great severity The advice and assistance of staff physicians of the U S Public Health Service and consultation and assistance of the medical advisory committee were obtained in establishing these guides They are constantly under examination in the light of experience to insure that they are realistic and reflect advances in medical knowledge These guides have been helpful in identifying cases of clear-cut disability and in describing the clinical evidence necessary to establish the existence and severity of these conditions

34 *Are copies of these criteria available to physicians?*

No At the present time they are not available In themselves the guides are not wholly representative of all the considerations taken into account in making a determination of disability They do not contain transmittals issued subsequent to the preparation of the guides, understandings resulting from individual case discussions, etc Neither do the guides fully represent the weight given to nonmedical factors in adjudication Regulations are being developed which will indicate to the public the basic criteria for eligibility

35 *What medical proof of disability is the applicant required by law to furnish?*

The pertinent provision of the law states "An individual shall not be considered to be under a disability unless he furnishes such proof of the existence thereof as may be required' The applicant is required to obtain, at his own expense, sufficient medical evidence from which a determination in his case may reasonably be made by the review team Individual medical examinations, records, and other data that the applicant needs to prove his disability may not be paid for from OASI funds

36 *How do applicants obtain the required medical evidence to support their applications?*

In general applicants will ask a physician to complete a medical report form and mail it to the BOASI district office Other sources may be hospitals, institutions, places of employment, or public or private agencies, where applicants have been treated for their disabling conditions. Applicants may be requested to obtain medical evidence either by BOASI or by the state agency.

37. *What assistance do BOASI district offices provide an applicant?*

A primary function of a BOASI district office is to advise applicants of their rights and assist them to obtain the necessary evidence. The term "case development" refers to this function of the BOASI district office. "Development" does not imply that BOASI funds have been used to purchase medical evidence. When applicants are interviewed, either at a district office, an itinerant station, or their homes, possible sources of medical evidence are discussed in order to determine the source from which the most comprehensive data on the applicant's condition may be obtained. Applicants may also be assisted in completing a request for a medical report. Where special circumstances indicate, a district office may arrange directly with the source to present a report for the applicant. Occasionally a BOASI district office will help the applicant by copying the medical record or summary in possession of a hospital.

When the BOASI district office knows a physician's preference (personal visit by applicant or report form mailed) in the matter, the district office may suggest that the applicant follow the physician's preference. When advisable, the district office may also telephone a physician to request a report on behalf of the applicant.

38. *When may an applicant be required by a BOASI district office to obtain additional evidence?*

BOASI District Offices may require the applicants to furnish additional medical evidence when a report is grossly inadequate, as when:

a. Evidence submitted deals with a condition other than the alleged disability, or

b. In old disability cases, the report does not contain any information as to onset, or

c. The medical report contains only a one or two word diagnosis, or

d. When additional evidence is needed which can be best secured by the district office through the applicant.

39. *Are applicants requested by the BOASI district office to obtain medical evidence of disability although there may be some question as to whether he meets the work requirements?*

Yes. For example, medical evidence is required and the case referred for a determination even though the applicant does not have a record of at least 1½ years of work in covered employment in the 3 years just before the date on which the applicant alleges his disability began. Ordinarily such an applicant would not be considered eligible. However, consideration of all evidence in the file may lead the review team to decide that the date on which the applicant alleges his disability began is incorrect and the applicant is, therefore, eligible.

40. *To whom does the term "reporting physician" refer?*

A reporting physician is the doctor who submits a medical report on the applicant's disability. He is usually the applicant's attending physician but sometimes where the disability is of long standing he may be a doctor who is not now treating the applicant but who has done so in the past.

41. *What is an applicant's principal source of medical evidence?*

An applicant sufficiently disabled to qualify under this program will probably be receiving medical care, or have had a medical examination for his condition. Ordinarily, a written report by the reporting physician based upon his existing records or a current examination of the patient will be sufficient.

42. *What information should a medical report contain?*

A medical report should be a concise, factual statement of clinical findings and medical facts by which the state agency's review physician or medical consultant can confirm such findings and arrive at a sound conclusion as to the severity of the impairment, thereby determining whether the applicant meets the medical qualifications for disability. The pertinent history, symptomatology, clinical findings, and diagnosis should be reported in sufficient detail to permit another physician to establish, from the report, the degree of severity of the applicant's impairment. Reporting physicians are not asked to express opinions as to whether or not the applicant is disabled in terms of either the degree of severity of the impairment, or work capacity, or employment potential of the applicant. These determinations are the responsibility of the review team, not the reporting physician.

43. *Is the use of official medical report forms mandatory?*

No. A basic form is provided. However, physicians may use any other form or prepare a narrative statement, incorporating the necessary information, on their personal letterheads.

44. *To whom are medical reports submitted?*

Physicians should mail medical reports to the requesting office (BOASI or state agency). The return address will be furnished with the request.

45. *Under what circumstances may a reporting physician be asked to supplement or clarify one of his reports?*

When a report fails to provide sufficient information to establish the severity of impairment, the review physician or medical consultant may write or call the reporting physician for additional data. Occasionally the patient himself will receive official notice that additional medical evidence is necessary.

46. *If the reporting physician cannot supply the supplementary data requested from his existing records, what procedure should be followed?*

If such data cannot be supplied without further examination of the applicant, the physician should so inform the applicant and discuss with him the necessary procedures and costs for developing the required data.

47. *What happens when an applicant fails to furnish additional medical evidence or to submit to a medical examination as requested by the state agency?*

Thirty days after the last request for additional evidence is made by the state agency, a determination will be made on the evidence in the file and the file sent to the division of disability operations, Bureau of Old-Age and Survivors Insurance, Baltimore. If an applicant fails to submit to an examination, he is allowed to explain his failure and a decision is made on all the facts in the case

48 *To whom is medical evidence available which has been provided by the applicant?*

Generally, medical information cannot be disclosed to anyone without the consent of both the applicant and the source However medical evidence is routinely made available to state vocational rehabilitation agencies for rehabilitation purposes

49 *Is there a specific provision in the law under which BOASI or a state agency may authorize the payment of OASI funds for medical examination or records required of an applicant to initiate and support his claim under the OASI disability program?*

No The basic responsibility for initiating and supporting his claims rests on the applicant

50 *By what authority does BOASI or a state agency expend OASI funds for medical examinations or records?*

Authorization for medical consultation is derived from the statutory authority granted the Secretary (1) to adopt reasonable rules and regulations to provide for the nature and extent of proofs and evidence, and the methods of taking and furnishing the same to establish benefit rights, and (2) to hold such hearings and conduct such investigations and other procedures as he may deem necessary and proper for the administration of the act

Similar statutory provisions have for many years been construed to authorize the use of government funds for the purchase of evidence, including medical evidence

51 *Under what circumstances may OASI funds be expended for medical examinations?*

OASI funds may be expended for medical examinations when the applicant has submitted sufficient evidence to show there is a reasonable likelihood that the impairment meets the disability requirements and yet there is still some question whether a sound decision can be made In such case, a medical (consultative) examination, at government expense, may be authorized by the state or federal review physician in order to insure that an improper award will not be made

52 *What is the purpose of a consultative examination?*

Consultative examinations are authorized for the purpose of

a Verifying the medical proof of disability that an applicant has submitted, or

b Providing additional medical details needed to confirm the diagnosis or establish the severity of the applicant s present condition, including measurement of the extent of his remaining functional capacities or the potential remediability of the condition

53 *Who determines the type and scope of a consultative examination?*

The state review physician makes these decisions in light of the particular circumstances of the case A consultative examination may vary from a simple laboratory test to a complete medical examination, including work evaluation and complete diagnostic services

54 *By whom are consultative examinations performed?*

These examinations are performed by consulting physicians selected by the state review physician The degree of participation by the applicant's physician in the referral of his patient to a consulting physician depends upon the policy of the state agency In selecting consulting physicians, the review physician is expected to conform to the customary practice of the state agency or follow the procedures he believes most suitable to the local conditions consistent with the maintenance of good doctor-patient relationship

55 *What medical information from the applicant's file is made available to a consulting physician?*

Any information necessary to an effective examination can be furnished to the consulting physician

56 *What expenses other than professional fees are payable from OASI funds in connection with consultative examination?*

When the physical condition of the applicant warrants, transportation costs and other directly related and necessary expenses may be paid Travel expenses of the consulting physician may also be paid when the applicant is unable to come to the physician's office Hospitalization of the applicant for observation and tests, but not for treatment, may also be provided Any expenditure must be authorized in advance by the state agency

57 *To whom is medical evidence available which has been obtained at government expense?*

Such information may be made available to the applicant's attending physician upon the request of the applicant and the consent of the consulting physician

58 *Is it an administrative policy at the federal or state level that the consulting physician be mutually acceptable to both the applicant s attending or examining physician and the review physician?*

No The basic policies are (1) noninterference in doctor-patient relationships and (2) conformance to existing state agency practices and procedures consistent with local conditions State agency practices vary Many of them consider acceptability to attending physician when selecting a consulting physician

59 *Are there any statutory provisions which prevent either the federal or state agency from adopting such a policy?*

No

60 *Can the federal or state agency pay the applicant s attending or examining physician for professional services in developing additional medical details needed to confirm the diagnosis or to establish the severity of impairment, after the applicant has submitted, at his own expense, sufficient evidence to show there is a reasonable likelihood that the impairment meets the disability requirements?*

Yes The state agency has the responsibility for deciding what evidence is needed and the best source of the evidence There is no prohibition on the use of the attending physician in a consultative capacity, however, in many cases, an examination by an independent medical source is considered preferable by the state agency

VA MEDICAL CARE PROGRAM

In the Oct. 27, 1956, issue, THE JOURNAL printed the text of an address presented by Louis M. Orr, M.D. Chairman of the Committee on Federal Medical Services of the Council on Medical Service, entitled "To Socialized Medicine and Socialism by Way of the Veterans Administration." This address has since been published in pamphlet form under the title 'The Trojan Horse' and may be obtained from the Public Relations Department of the A. M. A.

THE JOURNAL has received a letter from Robert A. Bell, M.D., medical consultant, National Rehabilitation Service, Veterans of Foreign Wars of the United States, disagreeing with both the policy and the philosophy of Dr. Orr's statement and with certain statistical material quoted in the address.

Since Dr. Bell takes issue with policies of the American Medical Association referred to the Committee on Federal Medical Services for action, his letter was forwarded to that committee for comment. Dr. Bell's letter and a reply prepared by Dr. Orr follow.—ED.

To the Editor:—This pertains to a manuscript which was presented before the annual meeting of the Louisiana State Medical Association, April, 1956, by Louis M. Orr, M.D., and reprinted in THE JOURNAL (162:860-865 [Oct. 27] 1956). The theme of that manuscript appears to have been impending socialized medicine and socialism through federally financed and controlled medical care of veterans with non-service-connected disability, in the VA hospital and medical system.

I would not take issue with the right of any individual to express his viewpoint on the question under consideration but do plead for clarity, facts, and avoidance of bias in discussion of the problem. Dr. Orr was correct in stating that the American people must decide what is to be the future course of the VA hospital and medical care program, but there is reason to question the correctness of his implications that such decision has not and is not being made, that it must be made soon or it will be too late, and that if the program is not reversed we will eventually reach socialized medicine by default.

The hospitalization of veterans for non-service connected disability is effected in accordance with public policy. The governing statutes are enacted by the elected representatives in the Congress and approved by the President. Those who enact these laws are elected by qualified voters. We can only assume that the present program represents the consensus of current public opinion. The public, however, has not permitted or authorized an unrestricted hospitalization program.

The basic eligibility for treatment in VA hospitals for non-service-connected disabilities is now limited to some veterans of wartime service. Veterans of peacetime service must have been discharged from military service for disability incurred in service or must be in receipt of compensation for service-connected disability. Further, in the case of a veteran who has basic eligibility for wartime service, but was not discharged for disability and has no service-connected condition, there is the added requirement of a statement, under oath, of inability to pay the prospective cost of such treatment.

The war veteran (one who has had at least 90 days of continuous service, some of which was during a war period, from which he received a discharge other than under dishonorable conditions) who was not discharged from military service for disability and who has no disability adjudged by the VA to have been incurred in service or aggravated thereby, has no eligibility unless he certifies under oath that he is unable to pay for his prospective hospitalization and then, on a bed available basis. To state these eligibility requirements in another way, a veteran is not eligible for VA hospitalization for non-service connected disability merely because he is a veteran. The peacetime veteran has no eligibility unless he either was discharged from the armed forces for disability incurred or aggravated in service or is in receipt of compensation for such disability. The war veteran who was not discharged from military service for disability incurred in service, or aggravated thereby, and is not in receipt of compensation, has no eligibility unless he served more than 90 days, had a discharge other than dishonorable, and certifies under oath that he is unable to pay for his prospective hospitalization—and then, on a bed available basis, and subject to medical determination of need for such medical care.

It would seem that VA hospitalization for non-service-connected disability constitutes a public assistance program only for those disabled as a result of service, and for those war veterans who cannot afford, at the moment, the prospective cost of their hospitalization. This program hardly seems to have drifted from its original humanitarian purpose. It is a part of the over-all pattern of benefits, including compensation, pension, and readjustment aids, largely for war veterans, which has been established for the assistance and relief of eligible veterans as a measure of the government's obligation and therefore at the expense of the government. This program was instituted in 1924 by President Coolidge—an individual who would hardly be accused of having favored socialistic measures. In fact, the original program was far more liberal than is the restricted program currently in effect. The act of June 7, 1924 [Sub-Section 202 (10), Title II, Public, No. 242, 68th Congress] authorized, within the limits of existing government facilities, hospitalization for veterans of any war, military occupation, or military expedition since 1897, not dishonorably discharged, without regard to the nature or origin of *their disabilities*. The basic *policy presently in effect* was drafted into law (Section 6, Public, No. 2, 73rd Congress, approved March 20, 1933) in the depth of an unprecedented depression and it has not been changed materially since that time.

The hospitalization of a veteran for non service connected disability is contingent upon the availability of beds, and this is governed by, among other things, hospitals in being and by appropriated funds. The latter factor is reviewed periodically by the executive and the legislative branches of the government. Since 1948, when the Federal Board of Hospitalization was abolished, the Bureau of the Budget has consistently reviewed and coordinated the hospital, convalescent, and domiciliary programs developed and operated by the departments and agencies of the federal government Therefore, it is hardly correct to contend that the program has not been mandated by the American people

It should be apparent from the foregoing that the total number of veterans is not synonymous with the number of veterans eligible for hospitalization in the VA hospitalization program and that even war veterans are not unconditionally eligible for such care It should further be recognized that a high percentage of war veterans, because of income status and the "inability to pay' oath requirement, will be unable to obtain these hospitalization benefits

As of Nov 30, 1954, the VA hospital patient load included 53 5% who were receiving treatment for non-service-connected disabilities These patients, in addition to meeting other requirements, had signed an affidavit of inability to defray the cost of hospitalization Of this group, a number equal to 32 8% of the entire patient load was comprised of patients under treatment for 'chronic' disabilities, such as tuberculosis, psychosis, or other conditions which had kept them in a hospital for at least 90 days The remaining 20 7% of the entire patient load was being treated for non-service-connected disability which was categorized as "nonchronic,' and almost half of these (9 4% of all VA patients) were in receipt of or had formally applied for a VA pension for non-service-connected disability To receive, or be eligible for, such pension carries a double connotation of medical indigency 1 The veteran must have a condition which is permanently and totally disabling and which interferes with the earning of a livelihood 2 The veteran cannot have an income of more than $1,400 if single, or in excess of $2,700 if with dependents More than one-half of this group of veterans were hospitalized for cardiovascular disease, cancer, neurological disease, or arthritis, and it appeared likely that the majority would require prolonged or repeated hospitalization Another 1 2% of the total VA patient load had filed claims for a service-connected disability This left 10 1% of the total hospital load who were being treated for a non-service-connected condition and who were under treatment for less than 90 days The VA experience indicates that about one-fifth of them would actually be patients who presented chronic' illness The chronic nature of the VA patient load was reflected in some measure by the fact that 64 6% of the patients in VA hospitals on Nov 30, 1954, had already been on the hospital rolls more than 90 days, and 49% had been hospitalized for more than one year It is also significant to note that the President's Commission on Veterans Pensions found (April, 1956) that almost 30% of the present pensioners have no income other than their veteran's pension and that less than 2% have incomes which come close to the present annual income limitations of $1,400 and $2,700

In light of the foregoing, one might reasonably question the intent and perspective reflected in the A M A official policy statement, quoted in the manuscript in question, regarding "whether the federal government should continue to engage in a gigantic medical care program in competition with private medical institutions", and the further statement, "whether the ever increasing cost of such a program is a proper burden to impose on the taxpayers of the country", and the further statement that "preferential treatment for veterans with these non-service-connected disabilities cannot be continued indefinitely, in view of its detrimental effect on the health and the economy of the entire nation"

The "competition" is hardly financial where the patient cannot afford the care, and, if the hospital care is conceded to be a necessity—and no one seems to contend otherwise—then funds must be forthcoming from either charitable, local, or federal sources, and, it is difficult to perceive how this program can be detrimental to the health of the nation, and, certainly the program requires a smaller percentage of the total national income than was the case 20 and 30 years ago

Aside from these considerations, the basic law provides that the statement under oath of the applicant who is otherwise eligible shall be accepted as evidence of inability to defray necessary expenses of hospitalization The General Accounting Office has investigated the application in practice of this 'inability to pay' statement, and its first report, dated March 11, 1953, was interpreted as indicating a possible abuse of the 'unable to pay hospitalization entitlement The VA then issued, on Nov 4, 1953, Circular 11 placing in effect an addendum to VA form 10-P-10, requiring veterans to answer, when executing affidavits of inability to pay, questions about income and net worth The purpose of this addendum was to focus the veteran s attention upon the propriety of his making an affidavit of inability to pay

The General Accounting Office, in February, 1956, submitted a further report, in response to a request from the House Committee on Veterans Affairs, on the financial status of veterans hospitalized for non-service-connected disabilities This report covered an investigation of 25,500 persons hospitalized for non-service-connected disability in general medical and surgical hospitals, and indicated that 217 of these persons had annual incomes of $3,500 or more (of which 186 had dependents, 44 were hospitalized for more than 30 days, and 87 carried medical insurance coverage) Chairman Olin Teague of the House Veterans Affairs Committee noted the alleged abuse of the VA hospital program by a small percentage of veterans who falsely state inability to pay for hospitalization, and the Veterans of Foreign Wars has approved efforts to correct such abuses

The VA hospitalization program is intended for the care of those with service-connected disabilities and for war veterans with non-service-connected disabilities who are unable to pay for such care The modernization of this program and its development as we know it today have come about only in connection with and as an outgrowth of the development of great hospital centers in our contemporary society This has followed the advances in medical knowledge and the pattern of extension of general benefits to all of the population over the years Other than these considerations, the VA hospital program has not changed materially in 30 years In fact it has become more difficult to obtain hospitalization for non-service-connected disability because of tautened administrative practices and because the proportion of beds to eligible veteran population has greatly decreased

The factor that has changed is the large increase in number of war veterans due to three great wars within the span of almost one generation Nevertheless, the numbers of veterans who can qualify for VA hospitalization benefits has not increased proportionally because of the limitations on income eligibility and the over-all increase in per capita income in this country It is difficult to perceive of how anyone can read into this program a trend to socialism It is in fact nothing more than an extension to the federal level of benefits for a group to whom the nation as a whole owes a debt, on a basis not materially different from that accorded at the state or local level, to citizens who qualify under laws of compensation or need In compensation cases, it is, at the federal level, analogous to the hospitals of private industry, of the individual states, and of the municipalities where used for similar purpose, and, in non-service-connected cases, it is analogous to the use of hospitals of states municipalities, and charitable institutions for those unable to pay for services received

To my knowledge no major veterans' organization has ever recommended that VA hospitalization benefits be extended to dependents of veterans, to farmers, to industrial workers, or any groups other than veterans of war in need, or veterans with service-connected disabilities No major veterans' organization has ever supported socialism in any form, and these organizations have, on the contrary, been opposed to it The Veterans of Foreign Wars at its 57th National Encampment at Dallas, Texas, Aug 12-17, 1956 resolved, that 'we resist without compromise all socialistic schemes at home'

It would appear that in our society as we know it today there is no question but that citizens in need thereof should be accorded hospital benefits, at the expense of others where required The proper general approach to making such benefits available to all citizens without cost to others is to promote those measures which provide an adequate income for all persons Great progress has been made in this direction in recent decades Until this goal is reached, however, there will be needy individuals who will require public assistance in their hour of need The federal government, for reasons which need not be elaborated here, but which surely have not been intended to lead to socialism, is engaged heavily in according such assistance to all citizens, as in the federal support for local hospital construction, for medical school support, for residency training of physicians, for public health service programs, and for medical research, to mention a few

There are good reasons why needy war veterans should continue to look to the federal government for non-service-connected hospitalization benefits These men have served their fellow men in time of war above and beyond the ordinary call of citizenship They have given of their health, their resources, and their time when other citizens have not so served, and economic resources have never been drafted The war veterans have offered their maximum gift at a time when the country was endangered, and under this program they are only being accorded limited health benefits in their hour of individual need This is in accord with the traditional American concept, dating back to the days of the Pilgrim Fathers, that those who have rendered special service to their country are entitled to special consideration The citizens who served in World War II and the Korean war did so with the understanding that the type of limited hospital benefit in question constituted a part of the over-all pattern of benefits which were established for the aid and relief of eligible veterans as a measure of the government's obligation and therefore at the public expense

Finally, it perhaps is not amiss to consider the moral and psychological implications for the future of any severe curtailment or restriction of this program In these days of tremendous social unrest, when great efforts are being expended to influence men s minds and win their allegiance, it would seem the height of folly to endanger a restricted but humane policy and program which so fully expresses the goodness, the humanity, and the moral leadership of this great country If we are to expect our citizens of the future to give of their lives, if necessary, to protect that which we hold dear, then we must leave them a heritage of fairness, humanity, and recognition for special service unstintingly rendered

Robert A Bell, M D
Medical Consultant
Veterans of Foreign Wars
610 Wire Bldg
Washington 5, D C

ANSWER TO LETTER FROM ROBERT A BELL, M D, VETERANS OF FOREIGN WARS

Basically, Dr Bell argues (1) that the present Veterans Administration hospitalization program has a mandate from the people, (2) that this program is still fulfilling its original purpose, (3) that eligibility of veterans for non-service-connected care is strictly limited by law and VA regulations, (4) that the VA s non-service-connected load is primarily chronic in nature and therefore a legitimate federal responsibility, (5) that the VA hospital system does not compete with private medical institutions, (6) that the care of veterans with non-service-connected disabilities is a legitimate federal duty, (7) that the VA hospitalization program cannot justifiably be charged with tending toward or indicating a trend toward socialism

In each of these points, Dr Bell is in disagreement with the statements in the address, each will be considered individually below

1 *Popular Mandate*—Dr Bell's argument that the present program has a popular mandate appears to be based solely on the fact that it is legal Congress passed the enabling acts and has, year after year, appropriated money for the program, the Bureau of the

Budget reviews the program consistently, these agencies are the agents of the people—therefore, "the present program represents the consensus of current public opinion"

Answer A program does not have "public support" merely because it lacks concerted public opposition That continued existence of a federal program proves popular consent is an essentially naive position With the vast amount of legislation considered by Congress each year, the average citizen becomes aware only of those programs given intensive national publicity But, as stated, "the facts and philosophy behind the VA program have never been brought clearly to the attention of the American people"

The President's Commission on Veterans' Pensions (Bradley commission) spent a full year in intensive study of nonmedical veterans' benefits and concluded

"Our present structure of veterans' programs is not a 'system' It is an accretion of laws based largely on precedents built up over 150 years of piecemeal development The public at large has taken little interest and the laws have been enacted in response to minority pressure There is, at present, no clear national philosophy of veterans' benefits"

2 *Original Purpose*—Dr Bell believes the VA has not wavered from the original purpose of the veterans' hospitalization program, the program "is intended for the care of those with service-connected disabilities and for war veterans with non-service-connected disabilities who are unable to pay for such care" In evidence, he gives the legislative history of veterans' care, beginning with the World War Veterans Act of 1924

Answer In 1917, when medical care for veterans at federal expense was first authorized, it was for service-connected disabilities only In 1923, due to the large number of vacant beds in federal hospitals, non-service-connected neuropsychiatric and tuberculosis care was authorized for veterans of the Spanish-American War, the Philippine Insurrection, and the Boxer Rebellion In 1924, non-service-connected care was authorized for veterans of any war since 1897, regardless of ability to pay—still because of empty beds (This is the point at which Dr Bell's historical note begins)

In 1926, the 1897 limitation was eliminated, but, in 1933, non-service-connected care was limited to veterans with tuberculosis, neuropsychiatric cases, or permanent disabilities In 1934, the present eligibility standards were established, under which the main limitations are available facilities and the veteran's inability to pay

These six legislative steps, from 1917 on, were itemized in the talk, they are repeated to show that veterans' hospitalization was originally provided for service-connected ailments only Non-service-connected care was added later, not as a basic purpose of the program, but as a supplementary benefit, intended primarily to utilize vacant beds

In 1949, Col George Ijams stated in testimony before a Senate committee that President Coolidge only approved treatment of non-service-connected cases by the (then) Veterans' Bureau hospitals when persuaded it would be cheaper than treating them outside the federal hospital system In July, 1953, Mrs Edith Nourse Rogers, Chairman of the House Committee on Veterans Affairs, presented at a subcommittee hearing a history of non-service-connected care which indicated that President Coolidge's primary interests in veterans' care were (1) treatment of service-connected cases and (2) utilization of the 9,500 federal beds vacant in 1924

The Veterans Administration itself appears to be uncertain as to the program's present purpose Early in 1957, Administrator Harvey Higley, testifying before the House Committee on Veterans Affairs, asked Congress whether new beds should be built for service-connected treatment only and what the VA policy should be regarding new construction for non-service-connected care—questions which are certainly not justified by the law itself

The history of veterans' hospitalization makes clear that the original purpose was to provide care for service-connected disabilities Care for non-service-connected ailments is one of the Bradley commission's "accretions," a byproduct resulting from the desire not to let beds go empty But, if the public is not informed as to the true facts, past construction for non-service-connected needs will become a precedent for future construction, and the program may expand on an "open-end" basis, with no limit in sight except the total number of veterans in the population

3 *Limitations on Eligibility*—Dr Bell disputes the statement (1955 Hoover commission report) that the Veterans Administration medical care program has a potential of 21 million beneficiaries, the limitations on non-service-connected care make this figure an exaggeration (no alternate estimate offered)

Answer Five factors affect the provision of non-service-connected care The applicant must have a condition requiring hospitalization, wartime service (not 90 days minimum, as Dr Bell states, but any wartime service), and a discharge other than dishonorable, he must be unable to defray medical and/or hospital expenses, and there must be a bed available in some VA facility, not necessarily in his state of residence (in 1954 15% of VA patients discharged were hospitalized outside their own states)

Veterans may possibly be prevented by the first limitation from obtaining VA care for some minor ailments but it does not limit the potential number of beneficiaries, any veteran can, at some time in the future contract a hospitalizable illness At the beginning of this year, over 22,500,000 of the nation's 22,600 000 veterans had wartime service We do not have figures on the total number of veterans with dishonorable discharges, but less than 1 5% of the nearly 200,000 pension and compensation applicants in 1955 were rejected for this reason It seems obvious that these three "limitations" do not significantly reduce the potential patient load

Bed availability limits the amount of care which can be provided, not the number of veterans eligible for care—and the number of VA beds has been constantly expanding In 1940, there were almost 60,000 operating VA beds, in 1955, there were twice as many operating beds and 127,605 constructed beds Yet, according to the VA's own census (Nov 30, 1954), only 42,456 VA patients were then being treated for service-connected disabilities—less than the total beds 17 years ago Since 1940, the VA has made 60,000 new beds "available" for non-service-connected care

Obviously, when the number of eligible veterans increased, the number of VA beds followed suit, especially since our laws set no limit on VA hospital expansion In 1957 (as previously noted) the VA brought before Congress the question of further expansion

Ability to pay, therefore, becomes the significant factor in deciding the potential patient load But here the VA is not allowed, by its interpretation of the law, to determine eligibility, the veteran is his own judge Dr Bell says 'a high percentage of war veterans, because of income status and the 'inability to pay' oath requirement will be unable to obtain these hospitalization benefits " Income status is no barrier to entitlement, since there is no income level or, indeed, any objective standard by which it can be decided whether a veteran is able to pay The VA itself says that even the statement of assets and liabilities "may be used in no way whatever to deny hospitalization to a veteran " The statement of inability to pay is considered sufficient, and even overriding, evidence by the VA

How much meaning can this oath have, even to the honest veteran? The majority of patients sign it when applying for care—before diagnosis and treatment and before knowing how long they will be hospitalized They have no idea how much care will be needed, and certainly no idea of its cost or that of comparable private treatment A veteran in the middle-income group, with a family dependent on him, might (without any conscious dishonesty) decide he could not afford to pay for care which a non-veteran in similar circumstances would scrimp and save for or provide through voluntary health insurance—merely because the veteran has been convinced by years of speechmaking that he has "earned' lifetime special care

However you look at it, the "inability to pay" statement is an amorphous standard which, whatever else it does, does not automatically eliminate a "high percentage" of veterans Because it is a purely subjective gauge and because the veteran's judgment is based on inadequate knowledge of costs and of what he is really entitled to, almost any wartime veteran can convince himself he cannot afford private hospital care

I submit that the estimate of 21 million potential beneficiaries is quite valid Certainly the VA has not enough beds to hospitalize all 21 million simultaneously, neither does the United States have enough beds to hospitalize its 165 million, but we do not deny that any citizen is a potential hospital patient

Dr Middleton, chief of the VA's department of medicine and surgery, speaking before a subcommittee of the House of Representatives at the appropriations hearings on the fiscal year 1958 budget, said "We are confronted with the responsibility for the medical care, or possible medical care, of some 22 million veterans " The VA apparently accepts this as a valid estimate

As the veterans grow older and chronic diseases become more prevalent, more and more veterans will decide they cannot afford private care and more veterans will become actually eligible, by signing the oath Increased demand will lead to pressure for construction of more beds to accommodate these non-service-connected cases, this is the past history of the VA and it will be the future history, unless we act now

4 *Chronicity of VA Load*—Dr Bell quotes the VA figures which emphasize the "chronic' nature of the illnesses treated in VA hospitals, he seems to feel that, since so many veterans' disabilities are chronic (if we accept these figures), they are a legitimate federal responsibility

Answer The VA says "64 6 percent of the patients in Veterans Administration hospitals on November 30, 1954, had already been on the hospital rolls more than 90 days, and 49 percent had been hospitalized more than one year " Almost two-thirds of the daily patient load is, in other words, "chronic ' But only 32 8% of the patient load consists of "chronic" patients with non-service-connected conditions, the remaining 31 8% is a segment of the 38% treated for service-connected disabilities, 7 9% with service-connected disabilities but treated for non-service-connected ailments, and the 0 6% who were non-veterans, a total of 46 5% of the load Almost half the "chronic" cases have service-connected disabilities

Despite the emphasis on chronic cases in VA reports (the VA definition of "chronic" is discussed in a later section), roughly four patients of the VA with non-service-connected conditions are "nonchronic" to every six "chronic " But does chronicity, in itself, entitle a patient to federal aid?

The medical profession has never adopted the view that "chronic" patients should be federal wards In 1953, concerning the temporary exception to its policy on veterans' care made for neuropsychiatric and tuberculous disabilities, the A M A said, "The entire question of whether the care of these patients is a local or a federal responsibility must be reanalyzed by Congress (C)ommunity facilities must be developed under state or local administration for the benefit of all '

In November, 1956, the A M A advised the medical profession "While the present law exists, we should help assure that veterans whose illness constitutes economic disaster will not be displaced by those suffering short-term remediable ills that, at the worst, constitute financial inconvenience "

Here again exception is made in recognition of existing laws, not in principle The patient with a chronic condition is, admittedly, less likely to be able to pay than is the patient with short-term illness, but this probable inability to pay does not constitute an automatic lien on the federal government The question still remains "What is the proper source of care for the indigent patient?" Our answer still remains, "His own community '

In connection with chronic illness, it should be noted that the average age of the veteran patient is increasing In 1955, 15 8% of our veterans were 55 or over, and, by 1970, we will have over 2 million veterans aged 65 or more As the veteran ages, chronic illness becomes more likely and he is more likely to be unable to pay Is it not odd, therefore, that chronic disease accounts for a smaller part of the non-service-connected than of the service connected load? Might this not indicate that VA patients with non-service-connected conditions are admitted more on a basis of medical interest than of financial need?

5 *Competition with Private Institutions*—This disparity between the increasing age of the veteran population and the diagnoses prevalent among VA patients with non-service-connected conditions illustrates one area in which the VA is 'in competition with private medical institutions' Dr Bell implies that "competition can only be financial, if these patients say they are unable to pay, private medical institutions lose no money and, he says, the VA does not compete

Answer The American Medical Association does not oppose VA non-service-connected care merely because some VA patients might be able to afford private care The VA's competition with private institutions is much more basic, and affects the health of the whole nation

The nature of this competition was indicated at least three times in the address

(a) In 1953, the A M A discussion of neuropsychiatric and tuberculosis care requested congressional reanalysis of responsibility for this care, noted that "community facilities must be developed under state or local administration for the benefit of all," and pointed out the detrimental effect on the nation's health and economy of preferential treatment for veterans with these diseases

(b) In Cincinnati, where the VA was determined to open a new, unneeded general medical and surgical hospital in an area adequately supplied with general medical and surgical beds (VA and non-VA), in spite of an acute need and a possibility of staffing for neuropsychiatric beds, the VA plan did not meet veteran needs and would aggravate health personnel shortages for the entire population of the area

(In January, 1957, this hospital, with 39 tuberculosis beds, 78 neuropsychiatric, and 346 general medical and surgical, reported 40 tuberculosis patients, 70 neuropsychiatric, and 319 general medical and surgical One-sixth of the tuberculosis load had service-connected conditions, one-third of the neuropsychiatric load, and 18 of the 319 general medical and surgical patients, less than 6%)

(c) In the summation "Through the VA program we are siphoning off personnel and facilities needed to develop adequate health facilities for all the American people, including the veterans and their families in their home communities'

These are the ways in which the VA competes with private medicine as an alternate source of care for one eighth of the population, making less urgent the pressure on states and communities to provide adequately for their own citizens, by creating an artificial personnel shortage, and by creating two medical systems and two classes of patients and thus interfering with the development of better care for all citizens In addition, in its increasing emphasis on the acute non-service-connected case, it competes with nonfederal postgraduate training programs, which serve all citizens, not merely one class

The medical profession opposes, not competition for the patient's dollar, but competition for the taxpayer's dollar—because funds which have gone to the VA for treatment of non-service-connected cases and for construction of new VA facilities in which to treat them could and should have been spent at the state and local level for care of all indigent citizens and for adequate facilities for the whole community

Nonetheless, a comprehensive answer to the denial of VA financial competition must point out that the VA program is, in at least one facet, in direct financial competition with private physicians and hospitals The law says that veterans without service-connected disabilities are eligible only if unable to pay for care, yet the VA has consistently admitted and treated veterans for disabilities or illnesses covered by workmen s compensation and health insurance, and has presented bills for such treatment, a practice which the A M A considers unethical and in direct violation of the stated intent of the law During fiscal year 1955, the VA collected almost 4 million dollars from nonfederal sources for medical care, most of which was collected under hospitalization contracts

6 *Federal or Local Responsibility*—Care should certainly be provided for indigent patients, but we do not agree with Dr Bell that it is irrelevant whether it be provided at the local or federal level The A M A firmly believes that indigency is a community responsibility and that local administration is not only proper but also more efficient and more economical, as well as more fair to the citizen who is not a veteran, but is just as sick and broke as any man who served in uniform

Within the community, all patients who receive publicly financed medical and hospital care because of indigency should receive equal benefits, according to their need This is possible only when the community accepts its full responsibility and all care is administered at the local level, through local physicians and hospitals

Dr Bell considers VA care as 'nothing more than an extension to the federal level of benefits for a group to whom the nation as a whole owes a debt, on a basis not materially different from that accorded at the state or local level, to citizens who qualify under laws of compensation or need He considers veterans compensation (payment for service-connected disability) analogous to workmen's compensation in private industry and "in non-service-connected cases it is analogous to the use of hospitals of states, municipalities, and charitable institutions for those unable to pay for services received

Answer Here is the crux of the disagreement Must we divide our population into two groups, a privileged class who served in uniform and a "second-class group who did not, because of age, physical disability, essential occupation, or even the arbitrary choice of the Selective Service System? The Bradley commission feels that 'The Government's obligation is to help veterans overcome special, significant handicaps incurred as a consequence of their military service. The objective should be to return veterans as nearly as possible to the status they would have achieved had they not been in military service.'

This is a clear statement of the debt owed the veteran: full repayment for whatever adverse effect military service has on his future life. If non-service-connected care is payment of a debt, then all hardships a veteran encounters must be taken as resulting from his military service; we must believe that veterans are under a lifetime handicap—which most veterans themselves deny.

Arguments for non-service-connected care resemble that anomalous creature which is *neither fish nor flesh* nor fowl. If military service is the basis of entitlement, then the program is unfair to veterans who elect to pay their own way; if indigency is the basis, how does the veteran's indigency differ from the nonveteran's?

Service-connected compensation is not merely 'analogous' to workmen's compensation; it is workmen's compensation for injury sustained as an employee of the nation. Non-service-connected care is not merely "analogous" to local indigent care; it is indigent care, but, for some unspecified reason, as a federal *rather* than a *community responsibility*.

If veterans are a special class of citizens (which is contended by certain groups, and put in practice by providing special care for veterans only, at the federal level, without regard to the origin of their disabilities), then, by logical extension, why limit it to those who cannot pay? If the sole basis of this care is indigency, then the federal government has usurped a responsibility of the state and the community.

Citizens in need of hospital care should receive it, at the expense of others if necessary, and we should work for medical and economic progress for all. But progress toward health should be through the state and community, not as a federally regulated, administered, and organized program, independent of and in competition with local governments.

7. *Road to Socialism.*—Dr. Bell states that, to his knowledge, no major veterans organization has proposed broadening federal medical care coverage or supported socialism in any form. The A. M. A. has not stated or implied anything to the contrary nor was any group accused of such actions in the address.

Nonetheless, it is still true that one natural result of class legislation is that the nonprivileged classes desire equal benefits for themselves. Farmers and factory workers contributed to our war effort, often at sacrifice to themselves; in time of need, they may well ask why they must use up their savings, borrow or seek public aid for hospital care while the veteran without service-connected disabilities receives free care at their expense.

Continuation of the Veterans Administration's medical care program for non-service-connected disabilities and expansion to meet the expected increase in demand by eligible veterans certainly provides a pretext for this sort of pressure toward state medicine from nonveterans. Taking this pressure together with the VA's already great encroachment on the responsibilities of the communities and states, it is impossible to deny the danger inherent in the program. The medical profession does not accuse the veterans or the VA of planning or attempting to socialize this country—but, regardless of intent, the VA's present program and philosophy is well on the road which leads to that end. The American Medical Association is, therefore, attempting to persuade the public, veteran and nonveteran alike, to stop and read the sign-posts, before we reach the point of no return.

Statistical Disagreements

The questions of policy and philosophy discussed above are more important and basic than the statistical material used to indicate the magnitude and future trends of the VA hospitalization program. We will confine our comments, therefore, to the four factual arguments which Dr. Bell seems to feel contradict or militate against the address: (1) the VA one-day census of patients, (2) VA costs in relation to national income, (3) the General Accounting Office investigation of abuses, (4) VA beds in relation to veterans. (Paragraph numbers in the following section refer to the paragraphs in Dr. Bell's letter.)

1. *One-Day Census.*—"As of Nov. 30, 1954, the Veterans Administration hospital patient load included 53.5% who were receiving treatment for non-service connected disabilities." (Par. 9.)

This and the remainder of the paragraph is taken almost verbatim from the VA Administrator's report for fiscal year 1955, page 22. However, Dr. Bell has missed the breakdown of the other 46.5% of VA patients on page 21, which comprises 38% receiving treatment for service connected disabilities and 7.9% with service-connected disabilities but hospitalized for non-service-connected ailments, as well as 0.6% nonveterans. Added to the 53.5% quoted above, this 7.9% gives a total of 61.4% hospitalized for treatment of non-service-connected disabilities, as stated.

Size of Chronic Load. The VA considers the one day census a fair means of estimating the average distribution of the patient load, yet makes "certain observations" concerning the 20.7% cases classified as nonchronic and non-service-connected. The VA speculates that many of these will become chronic cases, either because they are disabled (degree of disability unstated) or because experience has shown that one tenth of these patients (2% of the total load) will require more than 90 days of care. The net effect of this speculation is to give the impression that there are more chronic cases than are listed under this heading in the census breakdown. Such a conclusion is out of place and misleading, since, if the one-day census method is valid (as the VA claims) it will not be when distorted by inserting predictions as to the future of individuals.

It should also be noted that a chronic illness is, for the VA, defined by the patient's hospital stay: any patient who spends 90 days or more in a VA hospital is considered chronically ill, although the 90 days may include "3-day passes" out of the hospital, diagnosis, treatment, and rehabilitation. Compare this with the non-VA chronically ill patient, whose condition is diagnosed and who is rehabilitated on an office or outpatient basis and is considered hospitalized only while he is in the hospital

2 *VA Costs and National Income*—Disagreeing on increasing VA costs, Dr Bell says, "certainly the program requires a smaller percentage of the total national income than was the case 20 and 30 years ago' (Par 11)

Federal sources state that national income in 1933 was 39 384 billion dollars and in 1955, 324 028 billion, the cost of VA medical and hospital care in 1934 was $37,038,000 and in 1955, $748,739,000 In the two decades, income increased about 8¼ times, VA medical costs over 20 times

Dr Bell may be thinking of the argument popular several years ago, that the VA expended a smaller percentage of the national budget than in the 30s—ignoring, of course, the fact that the comparison was between a peacetime and a wartime budget Even in terms of budgets, federal appropriations increased only about 9 times from 1934 to 1955, roughly in proportion to national income, and still very much out of proportion to VA medical increase

3 *General Accounting Office Investigation*—Dr Bell quotes this investigation to prove indigency for the majority of VA patients with non-service-connected cases—a question which neither the address nor A M A policy has disputed However, for the sake of accuracy, I should point out that the General Accounting Office report mentioned by Dr Bell (Par 13) concerns two surveys one based on investigation of 1,100 cases, to determine the financial condition of veterans who said they could not pay, and one based on 25,500 cases, to determine the accuracy of the veterans' statement of assets and liabilities In quoting the General Accounting Office report, Dr Bell has somehow combined the number of cases studied in the second survey with the conclusions drawn from the first, actually, the office reported 217 out of 1,100 (not 25,500) had annual incomes of $3,500 or more, 176 had net worths of over $5,000

4 *VA Beds in Proportion to Veterans*—Dr Bell Bell states (Par 14) that hospitalization for non-service-connected ailments is more difficult to obtain because of "tautened" administration and "because the proportion of beds to eligible veteran population has greatly decreased"

In 1926, when all 5 million veterans were unconditionally eligible for federal care, the system had 20,600 beds, in 1956, with a veteran population of 22,250,000, the VA had some 126,700 beds In the past 30 years, although the veteran population has increased only 4 4 times and eligibility has been "curtailed,' the veterans' hospital system has grown over 6 times as large

Conclusions

It is true, as Dr Bell points out in closing, that many veterans have been led to believe that they have a right to receive complete medical care for life in payment for the time they spent in uniform, whether or not they suffered any harm in service This is true to such an extent that some veterans consider the 'statement of inability to pay a mere formality

Yet the law is clear non-service-connected care is to be provided only in unused beds in "existing facilities', the primary purpose of the VA hospital system is the care of service-connected disabilities This should mean that, as long as we have sufficient beds for service-connected cases, no new construction is needed and non-service-connected care will be provided only in the beds left empty when all service-connected cases are admitted Yet the VA has, instead, built three times as many beds as it needs for all service-connected care and now asks Congress whether it should build more for non-service-connected cases We may well ask what Congress means by "existing facilities"!

Is this the program which has not changed materially in 20 years? Can we possibly accept the statement that "The public, however, has not permitted or authorized an unrestricted hospitalization program"? Would it not be more accurate to say that the program first authorized in 1917 and amended in 1923, 1924, 1926, 1933, and 1934 has grown almost beyond recognition, not only without the authorization but almost without the knowledge of the people?

"If we are to expect our citizens of the future to give of their lives, if necessary, to protect that which we hold dear, then we must leave them a heritage of fairness, humanity, and recognition for special service unstintingly rendered" The medical profession has never opposed the idea of fairness, humanity, or special recognition for special service It is for this reason the medical profession has worked unsparingly to improve the treatment program for veterans with service-connected disabilities

But is all military service special service? Is it fair to say that any man who wears his country's uniform in time of conflict becomes thereby a ward of the government? Is it fair to say that our future citizens must be bribed to defend their country?

Or is it more just and prouder to say, with General Bradley, that 'military service in time of war or peace is an obligation of citizenship and should not be considered inherently a basis for future Government benefits The performance of the DUTIES OF CITIZENSHIP cannot be expected to be painless or free from sacrifice We believe, with the Bradley commission, that "what best serves the Nation in the long run will be in the best interest of the Veterans' President Roosevelt, over 20 years ago, expressed the same idea when he said

' no person, because he wore a uniform, must thereafter be placed in a special class of beneficiaries over and *above all other* citizens The fact of wearing a uniform does not mean that he can demand and receive from his Government a benefit which no other citizen receives"

We believe that our veterans are free men, who fought to keep their country free, not mercenaries, whose bravery and loyalty depends on the amount of spoils promised them

Chairman, Committee on Federal
Medical Services

MEDICINE AND THE LAW

This is the 11th in a series of articles dealing with medical professional liability An editorial (page 360) and a chronological resumé (page 364) appeared in THE JOURNAL, *Feb 2 The preceding articles in this series have been published weekly in* THE JOURNAL *from Feb 9, 1957, to April 6, and since then intermittently*—ED

HOW STATE MEDICAL SOCIETY EXECUTIVES SIZE UP PROFESSIONAL LIABILITY

During the past five years, there has been an increasing amount of interest and discussion in medical circles concerning medical professional liability Personal opinions have been plentiful, however, authoritative answers on most phases of the subject have been few

Why are physicians interested in the professional liability situation outside their immediate geographical area? One reason is that judgments and settlements in one state may be used as a precedent for future decisions and settlements in others Another reason is that many physicians are in a quandary as to how much professional liability insurance they should carry This decision, a personal one for each physician, is affected, in part, by the trend of medical professional liability claims and suits over the United States

This is a report of the answers and attitudes of state medical society representatives, revealed in a survey on these problems It is one part of the over-all survey of professional liability made by the Law Department The other reports on the results of the survey will be published in this column in subsequent issues of THE JOURNAL

During the late part of the summer of 1955, a three-part questionnaire on professional liability was sent to the medical societies of the 48 states and District of Columbia Subsequently, this same questionnaire was sent to the Alaska and Hawaii medical societies Replies, although in some instances incomplete, were received from all except those in Alaska, Idaho, Louisiana, and Maine The questionnaire was answered by society secretaries, executive secretaries, chairmen of committees concerned with professional liability, attorneys for state societies, or insurance representatives Here is what they had to say on the subject

What are the most common causes of professional liability claims against physicians in your area?

Since the responses to this question are quite varied, they have been grouped in categories Table 1 shows the number of times each cause was mentioned

Excluding the miscellaneous category, it will be noted that approximately one-third of the causes listed have nothing to do with the medical care and treatment given by the physician They relate to the ability of the physician to "get along" with his patients and/or other physicians

What have been the effects of professional liability claims and suits on the reputation and on the practice of the physician involved?

A few medical society spokesmen explained that in the smaller communities in their state the effects of such claims and suits were more pronounced than in larger communities Two responses indicated that the effect depended upon the amount of publicity given the case A few responses disclosed that the effects were more adverse if the physician had previously been the subject of a professional liability claim or suit (table 2)

What has been the duration of the effects of claims or suits on a physician's practice and reputation?

The responses to this and the preceding question, although acknowledgedly only the opinion of the person filling out the questionnaire, would seem to contradict the widespread belief that a professional liability claim or suit seriously and permanently damages the physician's reputation (table 3)

Is professional liability insurance readily available in your state?

Without exception, all state society representatives replying to the questionnaire indicated that medical professional liability insurance was available to the physicians in their state Furthermore, all of them except two stated that it was not difficult to obtain One indicated that physicians in certain specialties had difficulty, and another said that difficulties had been encountered by physicians who had had a previous claim or suit brought against them

What are the limits of professional liability insurance carried by physicians in your state?

The limits of coverage listed vary widely within a state and within the different types of practice It would appear, from the answers given, however, that the average (median) coverage across the country for general practitioners is $25,000/$75,000 and for surgeons and other specialists $100,000/$300,000, this first figure in each instance representing the yearly maximum coverage for one claim or suit and the second figure, the yearly maximum coverage for all claims and suits

How many insurance companies write professional liability insurance in your state?

According to the responses to this question, there are at least 45 carriers writing medical professional liability insurance in the United States One company operates in at least 28 states, 26 companies are active in only 1 or 2 states, and the remaining 18 companies fall between these limits

Breaking these figures down, we find that, of the 18 companies, one writes insurance in 25 states, one in 20 states, one in 15, two in 14, one in 10, one in 9, two in 6, one in 5, four in 4, and four in 3

In nine states there is only one company writing such insurance, while one state has 19 active carriers The remaining states have between 1 and 19 carriers writing medical professional liability insurance

Thirteen state societies indicated that they have a form of group insurance for their membership One carrier writes this type of insurance in five states, whereas the other states' policies are underwritten by different companies

TABLE 1 —*Causes of Professional Liability Claims*

Causes	No of Times Listed
Poor results and/or failure in fields of	
Surgery	23
Orthopedics (including surgery)	14
X ray and therapy	9
Diagnoses	9
Medicine	8
Obstetrics and gynecology	6
Anesthesia	6
Eye ear nose and throat	1
Excessive fees and/or efforts to collect fees resulting in counterclaims	16
Careless remarks made by other physicians	13
Poor rapport between physician and patient	4
Abandonment	8
Miscellaneous	22

Does your association have a claims-prevention program?

Twenty-one societies stated that they have a claims prevention program California, Colorado, Connecticut, District of Columbia, Georgia, Kansas, Minnesota, Missouri, Montana, New Hampshire, New Jersey, New York, North Carolina, Oklahoma, Rhode Island, South Dakota, Utah, Virginia, Washington, West Virginia, and Wyoming

What does your claims prevention program consist of?

Of the 21 societies with claims prevention programs, 15 offer an education course to their members These societies are those in California, Colorado, Connecticut, District of Columbia, Georgia, Kansas, Montana, New Hampshire, North Carolina, Oklahoma, Rhode Island, Utah, Virginia, Washington, and West Virginia

Listed below are the other activities mentioned a one-day course held twice a year for new members, with lectures on problems relating to claims, one or two medical society meetings each year dealing exclusively with medical professional liability, discussions of professional liability hazards at county and state meetings, courses offered senior medical school students, round-table discussions for interns and residents, indoctrination lectures for new members on admission to the society, and panels of physicians and attorneys discussing the problem

TABLE 2 —*Effects of Claims and Suits on Reputation and Practice of Physician Involved*

Effects	No of States
None	20
Very little	10
Some	1
Varied	10
No answer	10
Total	51

In addition, many societies publish articles on the subject in their medical journal and distribute copies to their membership A few states, as part of their claims prevention work, are attempting to improve the safeguards of professional work in hospitals and to improve public relations and doctor-patient relationships

Does your association have a claims review program?

Thirty-one replies indicated that a claims review program was in operation at the state or county level Such programs exist in Arizona, California, Colorado, Connecticut, District of Columbia, Georgia, Hawaii, Kansas Kentucky, Maryland, Massachusetts, Minnesota, Mississippi, Missouri ,Montana, Nebraska, New Hampshire, New Jersey New York, North Carolina, Oklahoma, Oregon, Pennsylvania, Rhode Island, South Dakota, Tennessee, Utah, Virginia, Washington, West Virginia, and Wyoming

TABLE 3 —*Duration of Effects on Physician s Practice and Reputation*

Duration of Effects	No of States
Extend over several years	5
Not more than two years	1
Not at all lengthy a matter of months or weeks	32
Unknown	2
No answer	11
Total	51

What does your claims review program consist of?

The claims review programs are handled by claims review boards, committees, or administrators on a statewide or county basis These committees and boards consist of from 3 to 14 physicians Only one board had lay members, and this board had two such members The members of these committees and boards are usually appointed by the president or the council of the society for a period of one, two, or three years They review professional liability claims brought against the members and recommend whether the claim should be settled or defended Some of the boards or committees act only if requested to do so by the defendant physician Some permit legal counsel and representatives of the insurance carrier that underwrites the defendant physician's professional liability insurance to participate Some committees arrange for expert medical witnesses—others do not

Does your society provide expert medical witnesses in litigated professional liability cases?

Twenty-three respondents said that their societies did not provide such witnesses Twenty said that they would provide expert medical witnesses, and eight states did not reply to this question

The states providing expert medical witnesses are Arizona, California, Georgia, Illinois, Kansas, Kentucky, Maryland, Minnesota, Mississippi, Montana, New Hampshire, New Jersey, New York, North Carolina, Oklahoma, South Dakota, Tennessee, Utah, Washington, and West Virginia

Do any of the county medical societies in your state have claims prevention and/or claims review programs?

County medical societies in 15 states and Hawaii have claims prevention or review programs, and in 26 states they do not We have no information concerning the situation in the other nine jurisdictions Claims prevention and/or claims review programs have been established by county medical societies in Arizona, California, Connecticut, Georgia, Hawaii, Montana, New Hampshire, New Jersey, New York, Oklahoma, Pennsylvania, Tennessee, Utah, Virginia, West Virginia, and Wyoming

Does your state medical association provide its members with group insurance, or does it approve such insurance?

The members of 13 state societies may obtain a form of group professional liability insurance protection through their state societies Two state societies recommend to their membership two or more approved policies, and 28 societies do not do either of these things Eight societies did not respond to this question

Did your association ever have a group policy or an approved policy? Why were such policies discontinued?

Respondents in 23 states indicated that their state associations had previously had a group or approved policy, 22 said that they never had such policies, and 6 did not answer the question

Following are some of the reasons given for terminating these group programs The insurance carrier discontinued group coverage, no particular advantage demonstrated under the group policy, unsatisfactory experience, high loss ratio, not enough physicians participated, and group coverage held by state insurance department to be illegal

Two responses were more specific in answer to this question One stated that the physicians criticized the group program and grew resentful when the agent of the carrier pressured them to carry other types of insurance coverage The other said that the rates were too high, that all of the participating members were being penalized because of a few habitually bad risks, and that the insurance company paid off claims to prevent suits without consulting the society, contrary to their agreement

Did your association ever consider the adoption of a group professional liability insurance policy or approved policies?

Associations in 36 states have, at some time, considered the adoption of such policies, 7 never have, and 8 societies did not reply to the question

State the reasons for not adopting a group or an approved policy

Respondents of some of the state associations that did not adopt a group or an approved policy after considering it submitted the following reasons for the association s action members wanted insurance to be handled by agent of their choice, suggested agent or carrier not licensed in state, group insurance contrary to state regulations and insurance laws, physicians did not want to be dependent upon one company for this insurance, society did not want to say that one insurance carrier was better than another, advantages to participating in group insurance not demonstrated, and high premiums, no carrier would underwrite a group policy in the state, and society not of sufficient size to make adoption feasible

How many county medical societies in your state offer a group or an approved policy to its members?

A group professional liability insurance program is offered to the members of a county society in one state, while, in another state, some of the county societies offer a group program, and another county in the same state has approved two policies

Summary

State medical society officials executing the questionnaire expressed the belief that generally a medical professional liability claim or suit does not have a serious or extended effect on the physician s practice or reputation They also feel that professional liability insurance is generally not difficult to obtain Nevertheless, the state societies recognize the importance and seriousness of this problem, and many have adopted claims prevention and claims review programs It is interesting to note, however, that there are 31 review programs and only 21 claims prevention programs The responses to the questionnaire indicated a need for a more systematic and thorough type of claims prevention program in the majority of the states

MEDICAL NEWS

ALABAMA

First Annual Joint Meeting—The medical staff of Redstone Arsenal and the Madison County Medical Society were joint hosts to the first annual Madison and adjoining counties medical meeting March 27 at Redstone Arsenal, Huntsville About 100 doctors from the six county area and nine out-of-area guests attended Preventive Medicine in Action' was the theme for the day The trip to the water treatment plant had two special features an explanation of the fluoridation process and a demonstration of protective equipment in use at Redstone The group saw a demonstration of the procedures in preparing to fire the Corporal Missile At the Army Hospital, they reviewed the medical program and the occupational health service

The evening session began with a cocktail hour, followed by a banquet, at which Dr W H Stallings, was master of ceremonies Maj Gen John B Medaris, commanding general, Army Ballistic Missile Agency, commented on preventive medicine and occupational health services Dr Logan T Robertson, Asheville, N C, in an illustrated address, emphasized the importance of preventive medicine in today's rapidly growing industrial world

The president of the Madison County Medical Society is Dr Grady Huckaby The Plans-Arrangements Committee comprised Dr Burton S Shook, Dr Norton E Cowart, and Capt John White, M C, U S Army The Protocol-Decorations Committee comprised Dr Otis F Gay, Capt John Sims, M C, U S Army, and Dr A L Watson

CALIFORNIA

Personal—Dr Harold G Trimble associate clinical professor, Stanford University School of Medicine, San Francisco, recently toured the Far East to discuss tuberculosis therapy in the United States In New Delhi, he addressed the 14th International Tuberculosis Conference on The Dynamic Approach to Pulmonary Tuberculosis—1957 Later he lectured at medical centers and universities in Manila, Calcutta Bangkok, Hong Kong, and Tokyo Dr Trimble is a past-president of the American Trudeau Society and the California Tuberculosis and Health Association

Postgraduate Conference in Medicine—Stanford University School of Medicine will present a postgraduate conference in medicine from the afternoon of June 13 until noon, June 15, 1957 Registration is unlimited and will be open to doctors of medicine The fee is not known The conference will offer lectures and panel discussions presenting the practical approaches to common problems in cardiovascular disease, endocrinology, infection, and hematology Diagnosis and treatment will be emphasized Information may be obtained from the Office of the Dean, Stanford University School of Medicine, 2398 Sacramento St, San Francisco 15

CONNECTICUT

Professor Cowgill Honored—At the annual meeting of the American Institute of Nutrition in April, the annual Osborne and Mendel award was presented to George R Cowgill, Ph D, professor of nutrition, Yale University School of Medicine, New Haven The award consists of a cash prize and a scroll The citation called attention to Dr Cowgill's 'many pioneer and subsequent fundamental research contributions to our knowledge of the B-vitamins and of protein' Dr Cowgill received his Ph D at Yale in 1921 and has been a member of the Yale faculty ever since This award is named in honor of two distinguished scientists in the field of nutrition, Thomas B Osborne, former research chemist at the Connecticut Agricultural Experiment Station, New Haven, and Lafayette B Mendell, former professor of physiological chemistry at Yale Both men, now deceased, were Yale graduates

ILLINOIS

Chicago

Dr Newman Honored—Dr Louis B Newman, chief, physical medicine and rehabilitation service, Veterans Research Hospital, Chicago, has received the distinguished service award from the Illinois Institute of Technology for his outstanding service in physical medicine and rehabilitation Dr Newman received his M D from Rush Medical College in 1931, and an M E from Illinois Institute of Technology, in 1921 A former naval commander, he is also on the faculty at Northwestern University Medical School

Personal—The James Alexander Miller fellowship for the year beginning July 1 has been awarded to Dr John E Kasik, a senior assistant resident physician in the department of medicine at the University of Chicago The grant of $7,000 is made yearly by the association to support fundamental medical research in tuberculosis The antituberculosis drug, cycloserine, will be the subject of Dr Kasik's research ——Dr Maurice S Mazel, of Chicago, spoke on "Surgical Treatment of the Coronary Artery Disease Problem' at the 50th annual convention of the Philippine Medical Association recently held in Baguio City

Lasker Award to Dr Katz—The American Heart Association recently bestowed the Albert Lasker Award on Dr Louis N Katz, director, cardiovascular department, Medical Research Institute of Michael Reese Hospital The award consists of three parts, a check for $1,000, a gold replica of the Winged Victory of Samothrace, and a citation Dr Katz has been

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health Programs should be received at least three weeks before the date of meeting president of the American Heart Association and the Chicago Heart Association He was a founder and president of the American Association for the Study of Atherosclerosis, and he is permanent honorary president of the Inter-American Society of Cardiology

Chloroform and the Dedication of Guthrie Rock—Recently the Chicago Medical Society dedicated the relocation of a 40-ton granite rock of Laurentide glacier origin as a memorial to Dr Samuel Guthrie (1782-1848), the discoverer of chloroform The dedication took place in Pasteur Park, Wood and Congress streets Geologists estimated that the grey-red oval rock originated some 80 million years ago and that it was carried by the Laurentide glacier from the Waushara region in Central Wisconsin to Worth, Ill, a distance of more than 200 miles It was discovered in Worth in 1885 by Guthrie's grandson, Ossian, known as the father of Chicago's drainage system In 1903 Ossian Guthrie enlisted the aid of the Chicago Medical Society in an appeal to the South Park commissioners to have the rock placed at the lake front as a memorial Permission was granted, but when the rock arrived at the foot of Jackson Boulevard in 1904, the Park District refused to accept it The rock was taken to Rush and Ohio streets, while the controversy raged, and in 1912 it was placed in Washington Park, near 55th Street and South Parkway In 1931 the Chicago Medical Society attached a plaque describing its purpose A year ago the society undertook to have the rock moved to the West Side Medical Center, where it will be an inspiration to future as well as present members of the medical profession Doctor Guthrie, in 1831, isolated what Dumas three years later named chloroform It became known as Guthrie's sweet whiskey' Chloroform came into widespread use about 1847

INDIANA

Expand Medical Center Housing—Scheduled for completion early in 1958, an apartment housing unit is under construction at the Indiana University Medical Center, Indianapolis, as the first in a series of units designed to meet the housing problems of students and staff Plans also provide for a dormitory-type addition to the Student Union building, serving single students, and for additional apartment-type units in the future The four-story apartment building will provide 105 one-bedroom units The project is designed to alleviate a student housing problem at the Medical Center and provide additional housing for the first-year medical and dental classes which will be moved from the Bloomington campus to the Medical Center in the fall of 1958

Personal—Dr Josephine Van Fleet, formerly chief of laboratory service, Veterans Administration Hospital, Indianapolis, has been appointed director of the Bureau of Laboratories, Indiana State Board of Health, Indianapolis, succeeding Samuel R Damon, Ph D, who had served as laboratory director since 1946 —— Dr Naomi L Dalton, a native of Salem and graduate of Indiana University School of Medicine, Bloomington–Indianapolis, left Feb 20 for Vellore, India, where she will serve as instructor and anesthetist at Christian Hospital and College Dr Dalton was in practice in Bloomington from 1941 to 1953 and recently served as associate director of anesthesiology at Mississippi Medical College She will spend five years at the 560-bed hospital and college for medical students in South India

Dedicate Psychiatric Research Institute—Indiana's $1,500,000 building housing the Institute for Psychiatric Research was dedicated recently at the northwest corner of the Indiana University Medical Center, Indianapolis, adjacent to the state's Larue D Carter Memorial Hospital Dr John I Nurnberger is chairman of the department of psychiatry, at the School of Medicine Dr Daniel Blain, medical director, American Psychiatric Association, was principal speaker at the dedication Other speakers included Governor George N Craig, Dr Margaret Morgan, president Herman B Wells, of Indiana University, and Dr Nurnberger, who outlined the aims and objectives of the psychiatric research program The institute, a nonprofit organization, was established to receive gifts and other contributions for the support of research in mental illness

LOUISIANA

University News—Dr Derrick Brien Jelliffe, for the past two years in Calcutta, India, as WHO visiting professor of pediatrics at the All-India Institute of Hygiene and Public Health, has been appointed visiting professor of tropical medicine at Tulane University School of Medicine Dr Jelliffe has served as medical inspector of the Sudan Medical Service in Africa, as senior lecturer in pediatrics at University College in Ibadan, Nigeria, and at University College of the West Indies in Jamaica He is the author of Infant Nutrition in the Subtropics and Tropics' and founder and present editor of the *Journal of Tropical Pediatrics*, presently printed in London, although the editorial offices are at the Tulane Medical School

Course for Foreign Students—Specialized intensive courses in English and the basic sciences for the benefit of foreign students beginning graduate study in the medical sciences will be inaugurated by Tulane University School of Medicine, New Orleans, with the help of a five-year $182,000 grant from the Rockefeller Foundation William B Wendel, Ph D, professor of biochemistry has evolved a plan for a one-year intensive course beginning with English, advanced mathematics, and the principles of chemistry and physics in the summer In the final months emphasis will be placed on basic courses in biochemistry and on an introduction to a research problem The graduate school and the school of medicine will cooperate in offering the courses, which will be at the undergraduate or graduate level as needed

MICHIGAN

Research Center in Ann Arbor—Parke, Davis and Company recently announced the selection of a 50-acre site in Ann Arbor, near the University of Michigan campus, as the location for its new 10 million dollar medical research center The new structure is expected to be completed by early 1959 It will supplement the firm's present research facilities, directed by Leon A Sweet, Ph D, vice-president It is anticipated that the present staff of about 400 persons will be increased by "a substantial number of persons'

Personal—Wayne State University recently bestowed the honorary degree of doctor of arts on Dr Alfred Heacock Whittaker, Detroit, who has served as surgeon on the staffs of Evangelical Deaconess, Harper, Children's, and Detroit Memorial hospitals Dr Whittaker is also a commissioner on the Detroit City Plan Commission, president of Future Detroit, Inc, and medical advisor to the Franklin Settlement He is a former president and trustee of the Detroit Historical Society and the Economic Club of Detroit

Establish Physical Medicine Academy—Physiatrists in Michigan have organized an Academy of Physical Medicine and Rehabilitation incorporated under the laws of the State of Michigan The officers are Dr Max K Newman, president, Dr James W Rae, vice-president, Dr Frederic B House, secretary-treasurer, and Drs George H Koepke, Robert C Dean, and William C Schaefer, trustees The objectives of the academy are to promote the science and art of medicine and the betterment of public health through understanding and utilization of the functions and procedures of physical medicine and rehabilitation The registered office of the Academy has been designated as the University Hospital, 1313 E Ann St, Ann Arbor Communications may be sent to the Secretary, 326 N Ingalls St, Ann Arbor

MONTANA

FOREIGN LETTERS

AUSTRIA

Rare Injuries of Muscles, Tendons, and Periosteum — At the meeting of the Vienna Medical Society on March 1, H Schonbauer stated that functional impairment of muscles and tendons is usually caused by the passive stretching of a muscle with maximal tension Persons who are not physically trained or who are insufficiently warmed up in bad weather and aged athletes with degenerative manifestations in the tendons are likely to incur such injuries Damage to the sternocleidomastoideus muscle in wrestlers and erector spinae in hurdlers, divers, and pole vaulters need no specific treatment Major ruptures of the abdominal wall, caused by pushing and throwing during gymnastics and boxing, must be sutured Ruptures of the pectoral muscles and of the long biceps tendon, caused by throwing, wrestling, and weight-lifting and tearings off from the insertion of the triceps in fencers and throwers, occur These ruptures must be sutured Rupture of the extensor tendon in fingers occurs during ball playing and ruptures of the bending tendon during tug-of-war A tearing off from the anterior superior iliac spine is a common occurrence in juvenile runners Ruptures of the adductor and gastrocnemius muscles are therapeutically unimportant, those of the quadriceps tendon, common in football players and ice skaters, must be sutured, and those of the tendo achillis, common in football and tennis players, are becoming increasingly frequent in skiers

Ocular Injuries in Athletes —At the same meeting, K Safai said that, because myopic athletes are particularly susceptible to ocular injuries, this condition should be especially looked for in the medical examination of athletes About 5% of detachments of the retina are due to athletic exercises Persons with a tendency to retinal detachment may be allowed to swim but not to dive Before a rational operation for retinal detachment had been devised, a well-known diver became blind in one eye because of retinal detachment She did not give up diving, despite warnings, and became blind also in the other eye

Electrocardiographic Changes Associated with Cardiac Hypertrophy —At the same meeting, L Slapak stated that changes in the electrocardiogram may occur in well-trained athletes The differential diagnosis between these changes and those of pathological origin may be difficult The most important of these changes are a prolongation of the PQ interval of more than 0 2 second and a prolongation of the relative QT interval These changes are observed with the patient at rest When an extra load is placed on the heart, the tracings become normal and even subnormal measurements may be found A sure diagnosis of a cardiac lesion can be made only after placing a heavy extra load on the heart The loading test must be carefully performed A decrease in the ST interval of 0 1 to 0 15 mv is observed in young persons after exertion, but this is not considered abnormal if the interval returns to normal after a short time Changes in the T waves in athletes may consist of a primary decrease noted immediately after a slight extra load which lasts only for a few minutes and does not recur with a moderate or heavy extra load The one-minute peak after a one-minute overload and a so-called secondary decrease can be observed three to five minutes after an extra load This parallels the degree of cardiac fatigue It may be observed after a moderate or heavy overload placed on the heart of untrained persons and indicates that the limit of tolerance has been reached Its occurrence can be delayed by training Higher amplitudes with chest wall leads and a physiological incomplete right bundle-branch block may be observed in well-trained athletes This is not an abnormal sign Likewise, severe bradycardia, temporary Tawara's rhythm, or transitory atrioventricular dissociation may occur on a purely physiological basis in athletes

Cytological Diagnosis —At the meeting of the Austrian Gynecologic and Obstetric Society in March, H Kremer said that the reliability of Papanicolaou's cytological test depends on the care used in taking the smear and on the medical experience of the examiner The accuracy of early diagnosis of cervical cancer and of uterine cancer in situ was proved in 88 2% of the 10,688 patients who were examined by this method between September, 1954, and June, 1956 The two years were subdivided into three periods, with the same number of patients in each period The per cent of an accurate early diagnosis (84 8%, 86 6%, and 93 7%) showed a steady increase According to the results, cytology proved to be valuable for detecting cervical carcinoma The use of cytology by the practitioner is recommended since only a precise technique in securing the smear is required The smear itself must be examined by an experienced cytologist

Vitamin B_6 Levels in Patients with Carcinoma —At the meeting of the Austrian Society for Gynecology and Obstetrics in February, O Seeliger stated that the vitamin B_6 levels in the blood and tissue of normal mice and of those with carcinoma are significantly different Similar studies in man have not been reported Vitamin B_6 determinations in man had previously been made only in the feces and urine It was possible to determine the vitamin B_6 level in the blood of healthy women and of those with carcinoma only after a slight modification of the method of microbiological determination of Atkins and co-workers They used Saccharomyces carlsbergensis 4228 as a bioassay organism for vitamin B_6 determination in the blood of monkeys The determinations of the vitamin B_6 level in the fasting blood of healthy women and of those with carcinoma of the sex organs did not show significant differences A second group of patients was

---

The items in these letters are contributed by regular correspondents in the various foreign countries

given 50 mg of vitamin B_6 intravenously, and the changes of the vitamin B_6 level in the serum were determined after 5, 15, and 30 minutes and 1, 2, and 24 hours The highest values of vitamin B_6 were obtained after 5 and 15 minutes, respectively, whereas the main portion of the injected vitamin B_6 had disappeared almost entirely after two hours After 5 to 15 minutes, the vitamin B_6 levels in the diseased women were significantly lower than those in the healthy women

Properdin Titer—At the meeting of the Austrian Society for Microbiology and Hygiene in Vienna in March, Dr W Auerswald, of the Vienna University, reported on the effects of polypeptides of low molecular weight on the properdin titer of rabbits His preparation, which had been proved nonantigenic and phagocytosis-stimulating previously, induced, after intramuscular administration in doses of 2 mg, an increase of the properdin titer from 8 units per milliliter of serum up to 64 units per milliliter After 48 to 72 hours, the properdin level returned to the initial reading It is assumed that, contrary to lipopolysaccharides which are antigenic, this polypeptide preparation might be useful for stimulating the properdin system without antigenic side-effects

BRAZIL

Stellate Ganglion Block in Vascular Diseases of the Brain—Dr A Figueiredo reported to the Associação Paulista de Medicina on 340 patients with nonhemorrhagic symptoms of acute vascular accidents of the brain in whom he had performed a stellate ganglion block Of these patients, 256 had symptoms of cerebral thrombosis without complications, 30 had a history of cerebral thrombosis complicated by cardiac decompensation or by diabetes, and 54 showed signs of cerebral embolism In all cases a 1% solution of procaine was injected through the anterior route The minimum time elapsed between the onset of the vascular accident and the first block was two and one-half hours and the maximum time was three days The block was repeated in each patient at least 10 times On the first day it was repeated every four hours and after that twice daily The results obtained after the 1st and the 10th blocks were evaluated in relation to the motor recuperation and the mental behavior of the patient The results were better in patients in whom the infiltration was done during the first hours after the onset of the symptoms Of the 40 patients treated in the first 8 hours, 72 5% after 1 block and 85% after 10 blocks were benefited, of the 57 treated after 9 to 16 hours, 70 1% after 1 block and 77 1% after 10 blocks were benefited, of the 55 treated after 17 to 24 hours, 38 1% after 1 block and 54 5% after 10 blocks were benefited, and of the 188 treated after 25 hours, only 22 7% after 1 block and 29% after 10 blocks were benefited Thus 162 patients, or 48%, showed some improvement after 10 blocks The best results were obtained in patients with thrombosis without complication (improvement in 121 of 256 cases, or 47 3%) and in those with cerebral embolism (improvement in 41 of 54, or 75 9%)

The patients with thrombosis complicated by diabetes and those with cardiac insufficiency did not respond to the treatment Thus, of 30 such patients, in 2 there was only slight improvement and in 21 the symptoms were unchanged, 7 died during the treatment In 42 patients, an electroencephalogram was obtained, and in all of them before the first block it revealed slow waves of low potential in the damaged hemisphere In 14 patients an electroencephalogram was again obtained three to five hours after the block, and in 12 of these the slow waves had disappeared In the remaining 28 the electroencephalogram was repeated after the 10th block In only 2 patients was there an increase in the blood flow, but clinical improvement was observed in 10 Stellate ganglion block gives good results in patients with acute vascular accidents of the brain without hemorrhage or the complication of diabetes or cardiac insufficiency

Penicillin in Dementia Paralytica—Dr A B Fortes (*O Hospital* 50 645, 1957) states that he treated three groups of 30 patients with dementia paralytica The patients of the first group were given malariotherapy followed by penicillin and showed an improvement rate of 50% Those of the second group were given 1 million units of procaine penicillin G daily for 10 days and showed the same rate of improvement Those of the third group were given 2 4 million units of benzathine penicillin G on the first, fifth, and ninth days plus 500,000 units of potassium penicillin G, every 12 hours, or a total of 17 2 million units in 10 days This schedule gave an improvement rate of 83 3% and significant improvement in the serologic and spinal fluid findings The patients treated with penicillin shortly after the diagnosis was established showed appreciable improvement, becoming quieter, less delirious and less agitated Their body weight also increased The author believes that treatment with penicillin is superior to malariotherapy and that the relative efficacy of the different forms of penicillin should be evaluated

Restaurant Sanitation—In 1947, Dr D A Christovão examined the sanitary conditions of 1,568 eating and drinking utensils of restaurants in the central area of the city of São Paulo Only 14% of the coffee cups and one lot of glasses from restaurants were considered satisfactory (maximum of 100 bacteria per utensil) The large number of bacteria present on all types of utensils and the large percentage of lots in which pathogenic organisms were found, as well as the number of lots from which Escherichia coli were isolated, revealed the existence of a great sanitation problem In a new survey (*Revista paulista med* 49 385, 1956), the author has found practically the same situation This is especially deplorable in view of the fact that many other activities of the São Paulo State Health Department have shown great progress in the last decade

FINLAND

Operation for Sciatica—Dr E V S Koskinen (*Annales chirurgiae et gynaecologiae Fenniae*, supp 3, vol 46, 1957) made a follow-up examination of 104 patients with sciatica in whom herniation of the nucleus pulposus was treated surgically Not counting earlier attacks of sciatic and back pain, all patients had had on admission continuous pain in the leg of at least one year's duration (average 26 months) All the patients showed distinct lesions of the nucleus pulposus The occupation of 67 involved hard work, that of 20 semihard manual work, and that of 17 light work The postoperative follow-up period was one to five years It was found that the pain syndrome with simultaneous onset in the back and leg occurred most commonly as a consequence of trauma In this series, 41% were completely cured, 45% were sufficiently improved to resume work, and 14% continued to suffer from sciatica Leg pain disappeared entirely in 60% of the patients, and in 26% slight and intermittent pains occurred Back pain was completely relieved in 46%, slight intermittent back pain remained in 36%, and *continuous back pain persisted in 18%* Restricted flexibility of the back, a constant symptom prior to admission, persisted in 19% of the patients The percentage with scoliosis had dropped from 78 to 5 In patients with areflexia the return of the reflexes was slow

Otological Rehabilitation —A research section for rehabilitation of the disabled has been organized in connection with the Institute for Occupational Health on the initiative of the Ministry for Social Affairs A total of 1,472 disabled persons were examined there in a little over three years, of those, 219 (15%) required an otological examination They were classified by J S Lumio according to their disability (*Duodecim*, no 1, 1957) in the following manner 1 Persons whose principal disability was hearing loss Forty-seven persons, or 3 2% of all disabled persons, were in this group Of these, 26 were completely deaf and 21 severely hard of hearing 2 Persons whose principal disability was something other than hearing loss but whose hearing loss was definitely disabling This group consisted of people who were severely hard of hearing or unilaterally deaf 3 Persons whose principal disability was something other than hearing loss but whose hearing was depressed, though not to the degree of causing disability There were 93 persons in this group 4 Disabled persons whose hearing was found to be normal on examination or became normal after treatment There were 49 in this group

Further analysis revealed that of the total series 11 5% had hearing loss and *5 2% (66)* were *deaf or* severely hard of hearing Of those suffering from chronic otitis media, 17 required medical attention, and 2 of those were advised to undergo a radical mastoid operation Of those who were deaf and severely hard of hearing, 3 spoke intelligibly, 27 indistinctly, though the meaning could be understood, and 9 so indistinctly that no meaning could be made out Fourteen persons were excellent lip readers and 9 knew little or no lip reading, 27 disabled persons used a hearing aid, and 20 others were fitted with hearing aids Speech training was recommended to 3 persons, and occupational training was required by 120

Pulmonary Vascular Changes Associated with Patent Ductus Arteriosus —Landtman and Hjelt (*Annales Paediatriae Fenniae*, vol 3 part 1) reported on a series of 23 children with patent ductus arteriosus Lung biopsy specimens were taken at the operation before ligation of the ductus Similar specimens obtained at autopsy from 100 children who had died of causes unrelated to the heart or lungs served as controls All the patients with patent ductus arteriosus revealed histological changes suggestive of pulmonary arteriosclerosis These changes, which were confined to the small arteries and arterioles, consisted mainly of medial hypertrophy, intimal proliferation, and thickening of the tunica adventitia The lesions usually caused narrowing of the arterial lumen Alveolar fibrosis was occasionally seen Similar pulmonary vascular changes were not encountered in the control group There was no correlation between the degree of the histological changes and the clinical data on the patients These observations support the opinion that all patients with patent ductus arteriosus should be *operated on regardless of the severity of the symptoms* and clinical signs

ITALY

Neuroradiologic Congress —The Italian Neuroradiologic Congress was held in Modena in March Dr Decker, of the Neurologic Clinic of the University of Munich, Germany, demonstrated a new pneumoencephalographic technique The modification consisted in the fact that the air, introduced by spinal puncture, is followed fluoroscopically in its passage through the subarachnoid spaces and the ventricular cavities of the brain An amplifying electronic device is used to enhance the brightness of the screen, which is looked at through a binocular system Spot films are taken when desired A cineroentgenographic film of the screen may be made, with 50 frames a second being used The fluoroscopic control of pneumoencephalography has proved advantageous in that there is greater certainty of filling the ventricular system, it is not necessary to develop the films to ascertain the location of the air, films may be taken when the air lies in the desired spot, and the examination may be interrupted if a cerebellar pressure cone should develop

Dr Di Chiro, of Naples, presented a case thought to be the first one to be reported of retinocerebellar angiomatosis combined with deep cervical angiomas A 26-year-old man, blind since the age of 16, was hospitalized with signs of increased intracranial pressure, ataxia, and severe radicular pain in the left upper extremity Typical retinal angiomatosis was found A roentgenogram of the skull showed calcification of the walls of both eyeballs Left vertebral angiography revealed at least two angiomatous formations in the posterior fossa and two angiomatous sacs embedded deeply in the cervical region at the level of the third vertebral body Carotid angiography failed to reveal any supratentorial vascular anomalies The intense radicular pain in the left upper extremity was believed to be caused by the cervical angiomas pressing on the nerves of the brachial plexus

Drs Di Chiro and Catapano presented the results of a pneumoencephalographic study of 18 patients with dementia paralytica Dilatation of the ventricular system and/or of the subarachnoid spaces, the former a sign of central atrophy, the latter a sign of cortical atrophy, was found in all patients Dilatation was always bilateral, this is considered an important feature of the pneumoencephalogram in patients with dementia paralytica The pneumoencephalogram in these patients is fairly characteristic In one patient suspected of having an intracranial neoplasm, the pneumoencephalogram was characteristic of dementia paralytica, and this diagnosis was eventually confirmed The pneumoencephalogram is of great diagnostic value in borderline cases of dementia paralytica Furthermore, concomitant lesions, as in one of the authors' patients with a subdural hematoma, may be discovered by means of a pneumoencephalogram Dilatation of the ventricular system was more frequently found in older patients, whereas a high degree of widening of the subarachnoid spaces has been proved to be related to advanced mental deterioration, regardless of the patient's age The relation between age and dilatation of the ventricular system and between mental deterioration and widening of the subarachnoid spaces, proved by the authors in patients with dementia paralytica, is believed to be a general rule The pneumoencephalogram in aged patients who have retained their mental functions shows only enlarged ventricles in most cases The hydrocephalic child with enormous ventricular dilatation is often surprisingly active On the contrary, the subarachnoid spaces are found to be markedly widened in patients with senile and presenile dementia and in those with dementia paralytica

PERU

Cerebral Metastasis from Lung Cancer —Lung cancer is the malignant tumor that gives rise to the largest incidence of cerebral metastasis Ten cases of bronchogenic carcinoma with cerebral metastasis are reported by Jeri and Landa (*Revista de neuropsiquiatria,* vol 19, no 2, 1956) Four of the patients complained of respiratory and six complained of neurological symptoms Their ages ranged from 36 to 64 years, nine were men and one was a woman Six were heavy smokers The respiratory symptoms were cough, with or without sputum and thoracic pain The six patients complaining of neurological disturbances had little, if any, respiratory distress On radiologic examination signs of intracranial expanding lesions and of lung tumor were detected in all of the patients In seven patients cytological study of bronchial secretion followed by bronchoscopy was made In four of these the former procedure and in five the latter confirmed the diagnosis The neurological changes induced by the cerebral metastasis were headache in eight patients, convulsions in six, motor changes in eight, papilledema in six, and various degrees of cerebral amnesia in seven The changes were noted from 10 days to 6 months before consultation and in most patients had developed rapidly Laboratory studies were of little help in the diagnosis of the cerebral lesions The electroencephalogram was normal in three of five patients thus studied Nine patients died, most of them within 90 days after confirmation of the diagnosis Craniotomy was attempted in five, but four died shortly after the operation Six were treated by roentgenotherapy, only one of these was still alive at the time of writing The authors stress the importance of early diagnosis and complete removal of the primary lesion before metastasis occurs

Shock Therapy and Adrenal Function —In an attempt to clear up the status of the adrenal function of psychiatric patients, specially in those undergoing shock therapy, investigations on the uropepsin excretion, as an indirect index of adrenal function, were reported by M Vargas in the same issue Hourly determination of this enzyme was made in 46 patients suffering from diverse neuropsychiatric conditions other than schizophrenia and in 45 schizophrenic patients All the patients were men In those with schizophrenia and chronic alcoholism the average levels of uropepsin were found to be somewhat lower than normal In those with manic-depressive psychosis the uropepsin excretion proved to be higher during the manic and lower during the depressive phase In most patients electroshock stimulated the adrenal cortex, and the uropepsin excretion more than doubled The hypoglycemia induced by insulin also acted as a powerful stressor agent, since in almost all of the patients in a coma the uropepsin excretion rate rose to 132% over the basal figure The uropepsin excretion reached the highest levels in the first four hours after insulin injection and then began to drop slowly Late in the course of the treatment, after several applications of shock therapy, the stimulating effect on the uropepsin excretion shows marked diminution Combined treatment with electroshock and insulin increases the uropepsin excretion, even in those patients in whom only one type of therapy no longer results in cortical stimulation The author concludes that (1) the adrenals of the schizophrenic do not react in the same way as those of the normal subject, (2) hypofunction of the whole gland cannot yet be inferred, (3) it is more likely that some functions are diminished, some increased, and some unchanged, and (4) the basic physiological modifications of the adrenals in schizophrenia may be represented by qualitative disturbances in the steroidogenesis, though quantitative changes cannot be ruled out

Mammary Cancer —Dr Bedoya Hevia M advocates the performance of radical mastectomy followed by roentgenotherapy in the treatment of mammary cancer (*Ginecologia y Obstetrica,* vol 4, no 2, 1956) He believes that the more extensive operation requires further trial and long-term evaluation before being adopted in the routine management of this disease In suitable cases needle biopsy is routinely made on the day before operation Its performance does not prejudice the prognosis and may make the treatment safer If positive, radical mastectomy is carried out on the following day If negative, a frozen biopsy specimen is obtained with the patient under anesthesia, and a radical mastectomy is performed if the histological examination reveals cancer Blood transfusions are mandatory during the operation In a series of 54 patients, radical mastectomy was followed by roentgenotherapy in 50 and in the remaining 4 simple mastectomy and roentgenotherapy were used. Of the 50 patients, 21 survived for five years or more, axillary metastases being present, however, at the time of report in 13 of them. The extended operation in which the supraclavicular lymph nodes are removed is not advised by the author, because the presence of metastases in these nodes constitutes a contraindication for radical mastectomy. As to mastectomy with resection of the internal mammary chain of lymph nodes, the author believes that further experience is needed in order to determine its real value and precise indications. In the elderly patient who is a poor surgical risk, as well as in the patient with an ulcerated tumor, the author recommends simple mastectomy as a palliative measure. When isolated recurrences take place, they are surgically removed and roentgenotherapy is applied. The author has performed an oophorectomy in some of these patients with encouraging results.

Cancer of the Uterine Cervix.—At a meeting of the Peruvian Society of Obstetrics and Gynecology in October, Dr. Estevez L., of the National Institute of Neoplastic Diseases, said that pelvic exenteration in selected cases of cancer of the uterine cervix goes beyond being a palliative measure and is definitely curative. Of his series of 14 pelvic exenterations, 13 were total and 1 was of the anterior type. The operative mortality was 30.7%. Eighteen months after the operation, nine patients, including the one operative death, had died. Drs. Majluf T. and Napoleon Mattos R., of the same institute, reported on a series of 1,224 patients treated by irradiation. Of those, 19.2% could not be followed. Of the remainder, 49.5% died within four years, 43.5% survived over five years, 41.0% over six years, and 34.2% over eight years.

Obstetric Anesthesia.—At the same meeting, Dr. Lozano Pardo reported on 120 patients who underwent anesthesia and analgesia during labor. He tried three different mixtures: (1) chlorpromazine hydrochloride, meperidine hydrochloride, and promethazine hydrochloride, (2) chlorpromazine, meperidine, and scopolamine, and (3) chlorpromazine, pyrazolonic derivatives, and promethazine. The best analgesic effect was elicited by the second mixture, but the first proved to have the best sedative action. The results obtained with the third mixture were poor.

Eclampsia.—At the same meeting, Dr. Bazul M. and co-workers, of the Faculty of Medicine, described two patients with eclampsia in whom an abnormal increase of the blood levels of estrogens as well as a decrease of the serum calcium levels were detected. He suggested the possibility that the hypocalcemia and the attendant syndrome of tetany in pregnancy are likely to be caused by a parathyroid dysfunction, the excess of estrogens of placental origin tending to diminish further the serum calcium levels. Drs. Villamón F. and Valiente Preciado H. advocated the "lytic cocktail" given intravenously in isotonic dextrose solution in the treatment of eclampsia. Dramatic clinical response often occurs 24 to 48 hours after this therapy is started.

UNITED KINGDOM

Brucellosis in Children.—Although brucellosis is a relatively rare condition in Great Britain, Wallis, scrutinizing the records of 2,000 hospitalized children seen personally, found 10 cases, most of which presented diagnostic puzzles and in three of which diagnosis was made in retrospect (*Brit. M. J.* 1:621, 1957). All the patients, most of whom came from rural districts, had drunk unpasteurized milk, although in some cases it was from tuberculin-tested herds. Some of the patients were town dwellers who became infected during a summer vacation in the country. The chief manifestations of the disease were pyrexia, enlargement of the liver, lymph nodes, and spleen, arthritis, epistaxis, chronic abdominal pain, headache, constipation, and albumin or pus cells in the urine. An erroneous diagnosis of psychoneurosis was sometimes made. Wallis points out that agglutination and skin tests may be negative while the disease is still active, and hence the diagnosis may have to be made on clinical grounds alone. He states that the best method of prophylaxis is to eradicate the disease from cattle by inoculation of calves with a vaccine of attenuated Brucella abortus strain 19. Until this is done the second line of defense is compulsory pasteurization and compulsory reporting so that health officers can trace outbreaks of the disease. The threat of legal proceedings against the distributors of infected milk and the owners of infected herds should stamp out the disease.

Pituitary Implants of Radioactive Gold and Yttrium.—Symptomatic improvement or even arrest of mammary and prostatic carcinoma occurs in some patients after removal or destruction of the adenohypophysis. One method of destruction is to introduce a radioactive isotope into the pituitary gland through a cannula passing through the nose and the sphenoidal sinus. Stretton Young described the structural changes in the pituitary after the implantation of radioactive isotopes of gold and yttrium (*Lancet* 1:548, 1957). Pituitaries were obtained at autopsy from patients who had previously received radioactive pituitary implants for mammary or prostatic carcinoma. Irradiation varied from periods of 31 hours to 150 days. In no case did the implants cause complete necrosis of the pituitary. A minimum of about 70,000 r of gamma-irradiation appears to be necessary to cause necrosis in most parts of the gland, and cells adjacent to the capsule and those around blood vessels are more resistant to radionecrosis than those elsewhere. Chromophobic, eosinophilic, and basophilic cells appear to be equally susceptible to the necrotizing effects of beta and gamma-irradiation. On the basis of absence of mitotic activity there is no evidence of regeneration after irradiation.

Growing Life Expectancy.—The life tables volume of the Registrar General's Decennial Supplement for England and Wales, 1951, now published, shows that the life expectancy of a boy at birth has increased by nearly 15 years in the past 40 years; for a girl, the increase is more than 16 years. In 1910 to 1912, 120 of every 1,000 boys born and 98 of every 1,000 girls born died before reaching their first birthday. The corresponding figures for 1950 to 1952 were 33 boys and 25 girls The longevity of women has increased more than that of men At age 60, for instance, the life expectancy in 1950 to 1952 for men was about 14¾ years, an increase of only ¾ year on the figure of 20 years earlier, whereas for women the life expectancy was 18 years, an increase of 1½ years in this period Persons living in England have a higher life expectancy than those living in Scotland or Wales In rural areas the mortality, particularly for men, is much lower than the national average

Deaths from Tuberculosis and Cancer—Provisional figures for deaths in England and Wales, in 1956, issued by the registrar general, show that the total number of deaths from respiratory tuberculosis was 4,851, compared with 5,837 in 1955, giving a death rate of 109 per million persons This is a decrease of 17% compared with the previous year, and means that, since 1947, the death rate from respiratory tuberculosis has fallen by more than 75% The provisional death rate from all forms of cancer for men was 2,274 per million population and 1,891 for women, the 1955 figures were 2,252 and 1,873 respectively The rise in the rate for men includes an increase from 693 to 726 per million population for deaths from cancer of the lung and bronchus The corresponding rate for women increased from 106 per million in 1955 to 111 in 1956

Mental Disease Statistics—In the annual report of the Institute of Psychiatry of the University of London, an examination of the records of 11,000 mental patients is discussed Of the 9,000 patients admitted to observation units, just over 25% recovered quickly from short-lived disturbances, so that after two or three weeks they were able to return home Of those admitted, 7% died in the observation units Many of these were suffering from a confusional state, delirium, or other mental disease accompanying the later stages of physical disease From the first admission rates, it is calculated that, of every 1,000 babies born, 53 will be admitted at least once in their life to a mental hospital, 10 of these will suffer from schizophrenia, 11 from manic-depressive and involutional psychoses, 24 from psychoses of old age, 2 from organic psychoses (excluding cerebral arteriosclerosis), and 6 from other mental disorders The first admission rates also show a striking difference in regard to the marital status of the patients In the group of men aged between 30 and 49 years, the number of first admissions per million was 1,455 (±196) for single men and 299 (±38) for married men, the corresponding figures for women were 1,262 (±173) and 536 (±52) Moreover, single persons stayed in hospital for longer periods than married persons In brief, single persons were found to be more likely than married persons to enter mental hospitals, and, once in, they were less likely to reach the point at which they could be discharged

Enteritis from Tortoise—M E M Thomas (*Month Bull Min Health* 16 29, 1957) reports that in May, 1955, a Moroccan tortoise was introduced into a household in which there had been a pair of tortoises for the preceding two years Within a month the condition of the two older tortoises had deteriorated and they suffered loss of appetite, and all five children in the household suffered from acute enteritis The new tortoise was found to be heavily infected with a salicin-fermenting paracolon organism resembling Salmonella paratyphi B Feces were not examined until two weeks after the illnesses, but the tortoise type of paracolon bacillus was then isolated in pure culture from one child who was 18 months old The organism was probably an atypical member of the Arizona group

Fats and Coronary Thrombosis—In a paper read before the Manchester Medical Society, Dr J N Morris, the director of the Medical Research Council's social medicine research unit, stated that he was unable to trace any correlation between mortality from coronary heart disease and trends in fat consumption In his view, the marked variations in the mortality in western countries with comparable high-fat intakes were in accordance with the suggestion that total fat consumption was the critical factor Changes in the consumption of animal fat in Great Britain in the present century could be related to changes in the incidence of coronary atheroma as recorded at the London Hospital, but they showed no relation to the registrar general s figures on mortality from coronary heart disease The trend of consumption of butterfat in Great Britain showed less than no relation, as indicated by the steep increase in the number of coronary deaths since 1943 Changes in the intake of vegetable fats showed a closer relation to the mortality, and changes in intake of hydrogenated fat showed a still closer relation, except that the distribution of coronary mortality by social classes was not in accordance with the class pattern of margarine intake International evidence is even more contradictory In Norway, where there is high consumption of margarine, there seem to be fewer cases of fatal coronary thrombosis than in New Zealand where little margarine is eaten Are the Norwegians protected by eating fish? If so, this does not explain why Aberdeen reported twice the coronary death rate of Oslo In terms of total essential fatty acids, the only available data for Great Britain give no support to the hypothesis that the population is now suffering from an absolute or relative deficiency of these nutrients One possible explanation of the apparent anomalies of the present moment is that several dietary factors may be involved or that diet is only one of several causes of ischemic heart disease

Plastic Transfusion Sets—The use of plastic instead of rubber tubing has reduced the incidence of thrombophlebitis by about 50%, according to a report to the Medical Research Council (*Lancet* 1 595, 1957) The tubing used in the trials was made of polyvinyl chloride with added plasticizer and stabilizer In a comparable control series, the standard rubber sets supplied by the National Blood Transfusion Service were used Among the infusions lasting more than 12 hours, reactions occurred in 32% of those with the plastic sets and in 56% of those with the rubber sets The percentage of severe and moderately severe reactions was 18 for those with the plastic sets and 34 for those using the rubber sets The incidents and severity of thrombophlebitis increased appreciably with the length of the infusion for each set The superiority of the plastic set was apparent in each of the groups studied

THE LEISURE CORNER

GARDENING AS A HOBBY

One of the more agreeable consequences of pursuing the suburban way of life is to be found in the garden A garden is sensitive to the will of the caretaker, it has to meet the needs and the taste of the person who undertakes the responsibility for its care The physician who cultivates gardening as a hobby will find it both an art and a science, as well as a healthful and delightful outdoor activity

In gardening, soil management is, first of all, of the utmost importance Soil should be prepared with one of the animal manures, rot from stables or fecal matter from the chicken, sheep, or cow This should be thoroughly worked into the soil and can be used at the rate of 1 lb for every 3 sq ft Most garden soils are comprised of five intermingled components mineral substances obtained from the slow disintegration of rock surfaces, humus or decaying organic matter, large quantities of minute living organisms such as bacteria, protozoa, and fungi, water, which holds in solution the dissolved mineral salts, and air

Experts on gardening point out that fall is the best time to remodel a garden As summer dissolves into autumn, there is a noticeable feeling of change taking place in the garden Overcrowded iris or day lilies require digging or division, delphinium must be moved to sheltered spots, and storm-damaged trees must be repaired or thinned Also there are shrubs to be planted, there is a lawn to be redone, and there are fences to be built or paths to be paved

Almost every gardener takes pride in the beauty of his lawn Unfortunately, too many people fail to recognize that a lawn is not a matter of temporary planting —on the contrary, it is a matter of permanent planting An adequately prepared lawn, one planted for posterity, may be as permanent and luxuriant as the trees that cast their shade over it Many lawns that surround the attractive manor homes of England were actually planted more than 500 years ago In creating a successful lawn, provision should be made for adequate preparation of the soil before planting, selection of proper seed, and sowing, watering, and rolling Most home owners desire a lawn of luxuriant green turf which will withstand a reasonable amount of wear and can be maintained with a minimum expenditure of time and money Kentucky bluegrass will meet these requirements more completely than any other type of lawn grass under average conditions of care and maintenance However, Kentucky bluegrass has several definite requirements for satisfactory growth It prefers a moderately cool climate, it requires a fairly fertile soil, it thrives best on good garden loam with a tendency toward heaviness, and it requires a soil with a pH ranging between 6 and 7 5

The term annual" is applied to flowering or foilage plants that give good results in a single season from seeds, such as petunia, zinnia, sweet alyssum, or castor bean Perennials have the added advantage of relative permanence Once planted, most perennials do not require resetting for three years Many of them produce springtime flowers, before the annuals appear above the ground, while most perennials produce plenty of bloom before late summer or fall

A few well-planted beds of roses within a small enclosure can provide a great deal of pleasure throughout the season Partly because of the special esteem in which the rose is held, partly because of the cultura requirements of the rose, and partly because the rose lacks the fullness of growth characteristic of some cultivated plants, it demands special compositiona arrangement In planning a rose garden, a few essential considerations should be kept in mind an enclosure that does not lack air and that gives shelter from the wind, a background wall or hedge from which the blooms may be seen to the best advantage and a geometric pattern to give the design definite form, so that the garden will have a beauty of its own When roses are cut for decorative purposes, they should preferably be cut early in the morning, before they have been affected for hours by the sun

Ever since the Alpine garden and the wild garden were introduced in England in the second half of the 19th century, the many possibilities of rock gardens have had a steadily increasing vogue At its best, a rock garden consists of a collection of Alpine plants in an environment closely approximating the conditions of their native habitat True Alpine plants grow in a stone soil that is moist but through which water passes readily The regions of our country which favor the development of rock gardens are found near the Great Lakes, the mountains and hills of the Appalachian chain, the rugged landscapes of New England, the Rocky Mountain states, and the Pacific Coast A site surrounded by an artificial atmosphere is inappropriate for a rock garden A rock garden should harmonize with the informality and casual character of natural foliage Honeysuckle, juniper, and Japanese yew are several of the shrubs suitable for a rock garden

The herb garden was one of the earliest expressions of garden art during the Renaissance Physic gardens at that time were planted within the cloistered walls of monasteries From these gardens the Monks dispensed a variety of medicinal herbs in an effort to alleviate the physical suffering and distress of their people This was a period when the enjoyment of plants for their beauty alone, while not entirely forgotten, was at least secondary in importance to their potential therapeutic uses Plants were regarded as a source of medicine, as a flavoring in cooking, as a source of color in dyeing materials, and in some instances for their fragrance alone Knowledge of these plants was general throughout the countryside, as is made evident by the wealth of plant names found in most European languages The many superstitions and the folklore surrounding such plants were passed on from one generation to another

Early colonial settlers in the United States brought with them a knowledge and understanding of the various uses of herbs, and before long many familiar Old World plants were flourishing in the villages and towns of New England In the 19th century interest in herbs declined steadily, and the herb garden as such became an almost forgotten thing of the past Within the past decade or so, there has been a reawakening of interest in the culture and use of herbs, so that once again many persons have begun to appreciate the quaint beauty and charm of the herb garden

Herbs are divided into several groups Aromatic herbs are grown for fragrance, culinary herbs are used as flavoring ingredients in cooking, and medicinal herbs still play a limited role in modern medicine, while herbs grown for coloring are incorporated in various dyes

Gardening is a delightful experience for many physicians Those physician-gardeners who own a small greenhouse are fortunate indeed, as they are able to carry on their gardening activities throughout the year New types of greenhouses have recently been designed along simple, efficient lines, greatly reducing construction costs A small greenhouse is now well within the pocketbook range of many gardeners Such an investment usually pays large dividends in both beauty and *relaxed, joyful activity*

MEDICAL FILM REVIEWS

Safe and Effective Oxygen Therapy 16 mm, color, sound showing time 22 minutes Produced in 1956 for and procurable on loan from Linde Air Products Company, 30 E 42nd St, New York 17

This film outlines the current procedures for administering oxygen by mask, catheter, tent, and hood The mechanisms by which the control of oxygen is maintained are stressed The use of oxygen in Isolettes and incubators is described, and the importance of observing the oxygen concentration in the incubator is brought out Intermittent positive-pressure breathing valves, aerosol, and high-humidity devices are also demonstrated and discussed The flow meters response to various types of back-pressure created by resistant apparatus and the adjustment for this are also shown Throughout the film, the necessary precautions against such things as excessive noise and combustion, as well as various possible sources for ignition, are stressed and discussed The importance of maintaining certain concentrations as ordered is brought out This film has been well prepared and is highly recommended for medical students, nurses, interns, and nurses aides

Fractures of the Shaft of the Femur 16 mm, color, sound, showing time 21 minutes Produced in 1956 by Churchill Wexler Productions, Los Angeles, for the Veterans Administration Procurable on loan from Central Office Film Library, Veterans Administration, Washington 25, D C

This film explains that, in treating fractures of the shaft of the femur, the surgeon is working against the pull of some of the strongest muscle groups in the body The film discusses the various means of overcoming the displacements caused by these muscles Treatment for fractures of the upper, middle, and lower portions of the shaft are demonstrated The principles of suspension traction as well as open reduction are illustrated, and the problems of after-care are considered Balanced traction is emphasized, which is proper for a film of this type The most widely used methods of internal fixation are demonstrated by diagram and by actual surgical illustration No attempt is made to present the more complicated surgical procedures The photography is excellent, with superb diagrammatic illustrations, and the narration is excellent This is a basic teaching film and should be of interest to all physicians who treat fractures It should be of specific teaching value for those in training and for general practitioner groups

Stapes Mobilization, Footplate Visualization Method 16 mm, color, silent, showing time 11 minutes Prepared by George E Shambaugh Jr, M D Eugene L Derlacki M D, and Wiley H Harrison M D, Chicago Produced in 1956 by Mervin W LaRue, Inc, Chicago Procurable on loan or purchase ($200) from George E Shambaugh Jr, M D 55 E Washington St, Chicago

This film depicts the technique of stapes mobilization, as developed by the authors, with photography of a complete operation from the injection of local anesthesia to the final dressing This technique emphasizes direct visualization of the footplate at 16 × magnification through the operating microscope The steps in the operation are demonstrated by means of endoscopic photography, and the motions of the mobilization of the stapes are well shown Of particular interest are the two sequences in the film which show clearly how the actual footplate of the stapes can be mobilized by this technique The sequence is very good, and clinical data, indications for surgery, and results are demonstrated by means of charts and audiograms This is an excellent film and should be of particular interest to otolaryngologists and otologists However, there may be interested practitioners, medical students, and audiologists who would like to view this for a better understanding of the physiology of hearing

NEW FILM ADDED TO A M A MOTION PICTURE LIBRARY

Principles of Respiratory Mechanics, Part II 16 mm color sound, showing time 21 minutes Prepared by Jere Mead, M D Edward P Radford, M D, Benjamin G Ferris Jr, M D, James L Whittenberger M D, Harvard School of Public Health, and Matilda C Smith, National Foundation for Infantile Paralysis Produced in 1956 by Science Pictures, Inc, under a grant from the National Foundation for Infantile Paralysis Procurable on loan (service charge $1 00) from Motion Picture Library, American Medical Association, 535 N Dearborn St, Chicago 10

This film uses both normal subjects and patients with asthma, pulmonary fibrosis, emphysema, and respiratory muscle paralysis to illustrate alterations in the mechanics of breathing produced by disease Models and animated drawings are used to illustrate pulmonary subdivision and such concepts as work of breathing and the value of mechanical measurements The pictures of normal and abnormal human subjects are supplemented with diagrams which show instructive laboratory experiments The two mechanical models are outstanding The organization of the picture is good, and the content is well summarized The photography is excellent It is a basic teaching film and should be most useful in courses on the physiology of respiration for medical students during the first or second year It should also interest physicians

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Lesions of Lung in Geriatric Patients Incidence and Surgical Mortality E J Beattie Jr J Am Geriatrics Soc 5 54-58 (Jan) 1957 [Baltimore]

Of 190 patients with pulmonary lesions that either required operation or could not be diagnosed, 79 were 60 years of age or older Of the 111 patients who were less than 60 years old, 33 had malignant tumors, 56 had pulmonary infections, and 22 had miscellaneous lesions Of 46 patients who were less than 60 years of age and who underwent thoracic operations, 22 had exploratory thoracotomy and lung biopsy, 17 lobectomy, and 7 pneumonectomy One of the 46 patients had ventricular fibrillation during the induction of anesthesia and died 36 hours after the operation Operative death rate was of 2 2% Of the 79 patients who were 60 years of age or older, 49 had malignant tumors, 17 had infections, and 13 had miscellaneous lesions, the commonest being pulmonary infarction The incidence of pulmonary cancers thus was 62% in the older patients as compared to 30% in the younger patients Of the 79, 47 underwent thoracic operations, 20 had exploratory thoracotomy, 13 lobectomy, and 14 pneumonectomy There were 4 operative deaths from pulmonary embolism, pulmonary edema, uremia, and pulmonary insufficiency respectively The operative death rate was 8 5%, as compared to 2 2% among the patients aged less than 60 years

Incidence of Complications Among Elderly Hospital Patients M Rang Lancet 1 401-402 (Feb 23) 1957 [London]

How do older patients fare in hospital? Are older patients less able to bear hospital discipline and procedures than young and middle-aged patients? Are they more likely to develop complications than younger patients? What complications occur in the hospital, and what proportion of patients are affected? In an attempt to answer these questions a survey was made of the complications arising during the 12 weeks from July to October in 2 geriatric wards, 1 for men and 1 for women, each with 30 beds All conditions arising during the survey that had been absent on admission and that were not clearly related to the patients' original disease were classed as complications During the period of the survey there were 86 admissions and 82 discharges Complications developed in 45 patients 12 of whom had more than 1 complication (60 complications in all) Four of the men and 2 of the women had been admitted to give their relatives a rest from home nursing In all 6 of these patients complications developed Patients in a general medical ward with 30 beds and 26 residents of a half-way house (a residence attached to the hospital for elderly persons) served as controls

Complications developed in 2 of every 3 patients admitted to a geriatric unit, whereas in a general medical ward complications developed in only 1 patient in 10 The complication interval (the time between complications for any geriatric bed) was roughly 11 weeks—four times shorter than that of either the general medical ward or half-way house Complications developed in 26 (39%) of the 67 women in the geriatric ward and in 19 (26%) of the 74 men, but the proportion of men in whom further complications developed was about twice as great as that for women Nearly half of the complications (26 of 60) were due to infection Four of 5 urinary infections such as "catheter fever" and pyuria developed after urine (sterile on culture) had been withdrawn by catheterization This cannot be blamed entirely on the nurse's technique, for the same nurses working in other hospital departments do not introduce infection Twelve complications were due to falls or to confusion Taking a slightly demented older person out of his home and putting him in a large ward, expecting him to climb in and out of a hospital bed, subjecting him to a routine that is strange and at times alarming, and asking him to try to walk with few and unfamiliar handholds puts a big strain on him A 4th of all deaths in the 2 geriatric wards were due to complications It is estimated that in a geriatric unit of 80 beds 1 complication may be expected every day and 3 deaths from complications each month

Pulmonary Tuberculosis and Diabetes Mellitus M T Warwick Quart J Med 26 31-42 (Jan) 1957 [Oxford, England]

The prevalence of pulmonary tuberculosis among patients attending the diabetic clinic at University College Hospital between 1940 and 1954 was 18 2 per 1,000 diabetic patients examined The prevalence among a sample of the general population was 4 9 per 1,000 The author reports observations on 104 patients with diabetes and active tuberculosis, about half of whom came under the care of a hospital for chest diseases and the rest of whom attended a diabetic clinic where tuberculosis was diagnosed during the course of their supervision There was a greater prevalence of tuberculosis among diabetic women than among diabetic men in practically all age groups up to the age of 65 In the group of diabetic patients

---

The place of publication of the periodicals appears in brackets preceding each abstract

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals Requests for periodicals should be addressed Library, American Medical Association Periodical files cover 1948 to date only, and no photoduplication services are available No charge is made to members, but the fee for others is 15 cents in stamps for each item Only three periodicals may be borrowed at one time, and they must not be kept longer than five days Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them over 65 years of age, diabetic men appeared to show an increased prevalence of tuberculosis compared with the control group, but no appreciable difference was demonstrated among the women Diabetes mellitus was the initial disease in 77 in this series of 104 patients, in 19 tuberculosis and diabetes were diagnosed simultaneously, and in 8 tuberculosis was diagnosed first No significant difference in the severity of diabetes was demonstrated between patients with and those without tuberculosis This finding differs from those of some other investigators Poor control of diabetes was more common in patients in whom tuberculosis developed This was particularly noticeable in the younger age groups A significantly higher proportion of diabetic patients in whom tuberculosis developed had had episodes of ketosis than that in other diabetic patients

Thus age, sex, control of diabetes and ketosis influenced the prevalence of tuberculosis No evidence was found to support the specific radiologic appearances described as 'diabetic tuberculosis' Twenty-five per cent of diabetic patients treated for tuberculosis before 1950 died from tuberculosis between 3 and 7 years from its onset but no patient in this study treated with antituberculous drugs has yet died from tuberculosis Factors influencing prognosis were control of diabetes, the initial extent of tuberculosis, and the method of treatment of tuberculosis

Portal Circulation in Portal Hypertension I Bergstrand and C A Ekman Acta radiol 47 1-22 (Jan) 1957 (In English) [Stockholm]

One hundred fifteen lienoportal venograms were made with an automatic film changer and by standardized technique in 88 patients, 70 of whom were studied in detail The 70 patients were subdivided in 2 groups, i e, group A comprising 16 patients with normal circulation in the portal system and group B comprising 54 patients with portal hypertension Of the 16 patients in group A who served as controls, 15 showed no evidence of liver disease or any disease involving the portal system and 1 man had a long history of heart disease, without signs of cardiac decompensation The spleen was not enlarged in most of the patients Of the 54 patients in group B, 6 had an expansive growth either involving the splenic vein or the portal trunk, with consequent extrahepatic portal obstruction, or the expansive process was intrahepatic, 36 had cirrhosis of the liver, 9 had extrahepatic thrombosis, and 3 had miscellaneous diseases Changes in the collateral circulation, the velocity of flow, and the width of the portal and splenic veins as observed in the lienoportal venograms of the 54 patients with confirmed portal hypertension were compared with those of group A

A filling of the collateral vessels, such as the short gastric veins, intercostal veins, coronary vein, inferior mesenteric vein, and the veins in the hepatoduodenal ligament, was regularly obtained in the patients with portal hypertension but never in the controls Filling of the collateral vessels was a sign of the circulatory change due to the increased pressure gradient between the portal and caval systems in all the patients Atkinson and co-workers found a collateral circulation to be a definite, though not regular, sign of increased portal pressure They claimed that the size of the collateral circulation in patients with portal hypertension is roughly proportional to the increase in portal pressure, such correlation was not found by the authors The velocity of flow in the portal circulation was practically always lower in the patients with portal hypertension than in the controls This finding was based on determinations made by measuring the spleen-hilum time, the spleen-liver time, and the emptying time of portal branches in seconds The widths of the splenic and portal veins were often increased in the patients with portal hypertension In patients with hepatic cirrhosis the accumulation of the contrast medium in the liver parenchyma was less dense and the hepatic veins were less frequently demonstrable than in the controls The method used in this study is accurate enough for the clinical diagnosis of portal hypertension

The Liver, Biliary Tract and Pancreas in the Aged An Anatomic and Laboratory Evaluation Z R Morgan and M Feldman J Am Geriatrics Soc 5 59 65 (Jan) 1957 [Baltimore]

The liver, biliary tract, and pancreas were studied on autopsy in 74 patients between the ages of 75 and 95 years in whom the clinical evaluation had not revealed any pathological conditions in the hepato-biliary-pancreatic system Lesions of the liver were found in 12 of the 74 patients, of these 3 had Laennec's cirrhosis, 1 primary carcinoma, 5 pronounced fatty degeneration, 2 congenital cysts, and 1 necrosis Thus the incidence of hepatic lesions was low The weight of the liver was determined in 72 of the 74 patients and was normal in 50 Most of the patients were not alcoholics, and that may account for the fact that only 3 had Laennec's cirrhosis The liver in older persons functions with a large margin of safety, and liver diseases are not a major cause of death Biliary stones were found in 27 of the 74 patients Pancreatic disease was not a major cause of death in this group of older patients Diabetes mellitus was present in 3 patients The spleen showed few, if any, pathological changes Splenomegaly was observed in 13 of the 74 patients and was associated with an enlarged liver in 4 Biochemical studies of the blood had been carried out in 19 patients during life, they yielded little information regarding the condition of the liver, gallbladder, and pancreas In older patients, functional changes in these organs are not measurable by ordinary methods of examination

Spectacular Effect of Deltacortisone on Postgastrectomy Deficiency Edemas P Vesin, P Frumusan and R Cattan Semaine hôp Paris 33 72-75 (Jan 10) 1957 (In French) [Paris]

The postgastrectomy deficiency syndrome is characterized by profound impairment of the general condition, with asthenia, loss of weight, and severe edema of the lower limbs and lumbar region, sometimes even anasarca, often accompanied by diarrhea The basic biological disturbance, in addition to hypochromic anemia, hypolipemia with hypocholesterolemia, and

Spectacular Effect of Deltacortisone on Postgastrectomy Deficiency Edemas P Vesin, P Frumusan and R Cattan Semaine hôp Paris 33 72-75 (Jan 10) 1957 (In French) [Paris]

The postgastrectomy deficiency syndrome is characterized by profound impairment of the general condition, with asthenia, loss of weight, and severe edema of the lower limbs and lumbar region, sometimes even anasarca, often accompanied by diarrhea The basic biological disturbance, in addition to hypochromic anemia, hypolipemia with hypocholesterolemia, and hypocalcemia, is the existence of pronounced hypoproteinemia and the decided reduction in blood albumin The administration of deltacortisone to 3 patients presenting this syndrome was followed by water and sodium diuresis resulting in the complete disappearance of edema and a definite improvement in the general condition, with restoration of appetite The rapidity with which these effects were secured contrasted strongly with the prolonged period needed when the customary methods of treatment (plasma therapy and milk given in divided doses) are used

The capital part played by aldosterone in sodium retention, as shown by the high level of urinary aldosterone found in all patients with chronic progressive edema, whether the underlying condition is nephrotic, cardiac, cirrhotic, or hypoproteinemic, formed the basis for the authors original suggestion that cortisone might inhibit the aldosterone hypersecretion and so lead to the disappearance of sodium retention and to sodium diuresis Various observations have since confirmed the importance of aldosterone in sodium retention and the value of deltacortisone in the treatment of edema Other studies, however, seem to show that the action of deltacortisone is indirect and that the reduction in aldosterone secretion is brought about by a hydroelectrolytic change, the nature of which is unknown The similarity between the various forms of edema—cardiac, cirrhotic, nephrotic, and hypoproteinemic—suggests that chronic edema should be regarded as a 'disease of homeostasis " The remarkable antiedemic action of deltacortisone and its beneficial effect on the appetite and the general condition make it exceptionally valuable in the treatment of deficiency edemas It should be supplemented, however, by standard measures, such as realimentation, milk therapy, plasma therapy, transfusions, and intravenously administered albumin, which are still indispensable to the restoration of the body s protein reserves

Relations between Arteriosclerosis and the Serum Cholesterol Level P David and E Eddie Union méd Canada 86 155-159 (Feb) 1957 (In French) [Montreal]

Serums of 720 patients were analyzed for cholesterol in order to establish the relationship between atherosclerosis and hypercholesterolemia The patients were divided into 2 groups (1) 392 with arteriosclerosis who suffered from angina pectoris, myocardial infarction, hypertension, and uncomplicated arteriosclerosis and (2) 328 with rheumatic or congenital heart disease or with diseases other than cardiac diseases Of the 1st group 146 (37 2%) and of the 2nd group 44 (13 4%) had a marked increase of their serum cholesterol levels The normal level in man varies from 132 to 300 mg per 100 cc, but the level in the individual remains nearly constant An increase of the total cholesterol in the blood may signify a passing of cholesterol from the tissue into the blood, whereas a higher serum cholesterol level may signify a migration of the cholesterol of the erythrocytes into the serum These modifications are due to the influence of the hypophysis, the gonads, and the thyroid

Hypercholesterolemia appears not to be indispensable for the formation or development of atherosclerosis, since many patients with this disease have normal serum cholesterol levels Disorders of the total lipid metabolism in patients with atherosclerosis might be reflected in the cholesterol metabolism Hypercholesterolemia, therefore, may indicate atherosclerosis, but this is far from being the rule, because many factors affect the cholesterol metabolism

Present Status of the Treatment of Ascitic Cirrhoses with Deltacortisone R Cattan and P Vesin Semaine hôp Paris 33 76-79 (Jan 10) 1957 (In French) [Paris]

Deltacortisone, which has an intense diuretic action and causes only slight sodium retention when given in standard doses, has been found to be useful in the treatment of patients with ascitic cirrhoses (excluding those in coma) In a series of 32 patients the drug gave complete relief of edema persisting after the withdrawal of deltacortisone in 14 and temporary relief of edema during therapy in 4 and failed in 14 These figures and those of others seem to show that 3 or 4 patients in 10 respond favorably to deltacortisone The effect of the drug, however, is unpredictable, and unexplained failures are frequent Two factors that may be significant in this connection are the presence of renal lesions and the existence of severe progressive hepatic insufficiency The best results are apparently obtained when the general condition is fairly good, although many patients in poor condition as a result of denutrition and anorexia have also been successfully treated

The effect of deltacortisone in edema is due primarily to its action on salt and water metabolism Diuresis usually begins during the first 3 or 4 days but may be late, appearing about the 8th day Consequently, treatment with deltacortisone should not be given up before 10 days have elapsed The quantity of urine excreted may rise from 500 or 1,000 cc a day before treatment to 2,000 or 3,000 cc or even more when diuresis sets in Interesting features of the diuresis are that it often occurs chiefly at night, that it leads to a rapid loss of weight, sometimes amounting to several hundred grams a day, and that, in spite of its intensity, it is not accompanied by thirst A factor of major importance in every patient in whom dehydration was secured and maintained after the withdrawal of deltacortisone was the urinary excretion of enormous amounts of sodium, leading to a negative sodium balance Hyponatremia, however, was never observed, on the contrary, the blood sodium level often increased as the edema regressed This sodium diuresis, without which dehydration is impossible, marked the end of the intense sodium retention found in these patients The mechanism by which the change was produced seemed to be the disappearance of adrenocortical hypersecretion of aldosterone with its powerful sodium-retaining properties

Contraindications to the use of deltacortisone are found chiefly in patients with a history of gastroduodenal ulcer, diabetes, or renal lesions (hematuria and azotemia) The presence of ordinary pyogenic or tuberculous infections is not a contraindication if the ppropriate antibacterial therapy is given at the same me Corticotherapy, when combined with antibi- ics, can often be used to advantage in the treatment infections, especially tuberculosis Deltacortisone is n ideal treatment for patients with edema and should e tried first unless contraindicated A suitable scheme f treatment would consist of an observation period f 8 or 10 days, with bed rest and partial suppression f salt in the diet, followed by the administration of eltacortisone in doses of 40 mg the 1st day, 30 mg the d day, and 20 mg the 3rd day and daily thereafter ntil dehydration has been secured The deltacorti- ne may then be withdrawn, but the patient should e kept under observation The weight in particular ould be closely watched, and an easy-to-follow salt- oor diet should be continued for some time Other ethods, such as a rigidly salt-poor diet, the use of ercurial diuretics, ion-exchange resins, and aceta- olamide (Diamox), must be used if deltacortisone ils to relieve the edema, but, even when these ethods are needed, deltacortisone may be continued n doses of from 10 to 20 mg a day because of its norexic and euphoriant effect

elf Healing, or Abortive, and Residual Forms of hildhood Leprosy and Their Probable Significance

B Lara and J O Nolasco Internat J Leprosy 4 245 263 (July-Sept) 1956 [New Orleans]

Of 347 children with leprosy observed at the Culion anitarium in the Philippines in the course of 24 years, 87 were studied for 2 years or longer after the onset f the disease Some of the children were born at the anitarium and others were still nonleprous when admitted with their leprous mothers Spontaneous, apparently complete healing occurred in 223 patients 77 7%) despite continued residence in the infected nvironment Incomplete healing—recurring exacerbations alternating with periods of incomplete subsidence of lesions—was observed in 36 (12 5%) The disease tended to progress in the remaining 28 (9 7%)

There was correlation between the process of healing and the clinical morphology of the initial or earliest recognizable lesions, as well as with the bacteriological, histological, and immunological features The incidence of complete healing of the lesions was highest among the patients with papulonodules and other definitely circumscribed, thickened initial lesions and lowest among the patients with the infiltration-like, more or less diffusely thickened initial lesions In patients with the wheal-like and the raised and flat macular lesions the incidence occupied an intermediate position There a fairly good correlation was found between low bacterial content of the lesions, strong reaction to repeated intracutaneous injections of lepromin (Mitsuda test), and a high proportion of healed lesions The correlation between clinical morphology and healing seemed to be even more consistent Concerning histological correlation, healing of lesions with undifferentiated, round-cell, or monocytic infiltrates occurred earlier than that of lesions with a tuberculoid structure, except for papulonodules

Relapses, when they occurred, were chiefly noted within less than 3 years of apparent healing, gradually becoming more rare after longer periods, and relapses were practically not seen at all after 10 years Relapses occurred more frequently in children whose early lesions showed a tuberculoid appearance on microscopic examination than in those with undifferentiated lesions They were also more frequently observed among the patients with wheal-like and macular early lesions than among those with papulonodules, lichenoid, or scar-like indurated lesions Eight patients showed inconspicuous, minimal, definite or suspicious signs of active disease, such as enlarged or tender nerve trunks, with or without anesthesia, and micropapulate or follicular residual lesions at or near anesthetic atrophic scars These residual lesions are likely to be overlooked in ordinary surveys, especially without the aid of previous records or history It is probable that most of them are benign but there is always the possibility that they and other undetected forms of apparently healed, or latent, primary infections may serve as sources for further dissemination *Continued observations on the development of lesions* in a group of children who while very young had been given repeated intracutaneous injections of lepromin were compared with those in a group similar in age and sex who did not receive lepromin injections Findings supported the earlier suggestion that lepromin injections in the form of the Mitsuda test may have protective value, especially when given to very young children

Infections in Leprosy Institutions

A R Davison Internat J Leprosy 24 275-279 (July-Sept) 1956 [New Orleans]

The concepts of some leprologists that leprosy is only or mostly, acquired in infancy and that it is unnecessary for adults to take even rudimentary precautions against infection are considered dangerous by Davison He describes the cases of 2 physicians, born in England, who acquired leprosy at the ages of 53 and 60 years while working as medical officers at a leprosy institution in Pretoria, South Africa, 3 Europeans who contracted leprosy as adults when working as overseers in leprosy institutions in South Africa, and 10 cases among adult Bantus who worked in leprosy institutions and contracted the disease at the average age of 46 years, although the onset of leprosy among Bantu males occurs generally at the age of 19 A plea is made for elementary hygienic practices by the staff in leprosy institutions

Another concept that is attacked by the author as dangerous is that leprosy can be contracted only after long-continued close contact He describes a case of leprosy in a male native child who was born of a leprous woman in an African leprosy institution The infant was removed from his mother 6 weeks after birth and had not been exposed to infection after that The first symptoms of leprosy occurred in the child 13 months later The author believes that infected persons should not come in contact with children and that breast feeding of children born in leprosy institutions is to be condemned

SURGERY

Mucosal Carcinomas as a Result of Irradiation D P Slaughter and H W Southwick A M A Arch Surg 74 420-429 (March) 1957 [Chicago]

The authors present 9 patients in whom carcinoma arose in mucous membranes included in a field of radiation therapy In 6 of these patients squamous cell carcinomas of mucous membranes developed in areas treated by external roentgen irradiation from 9 to 25 years before appearance of the tumors Each patient experienced late radiodermatitis in the skin utilized for the external port There was also fibrosis of the tissues between the skin and the affected mucosa There was microscopic evidence of radiation change in the mucosa and submucosa of all the cancer-bearing areas Treatment was unsuccessful, and the authors believe that this failure was due to the multicentric origin of the tumors, with new foci developing in the irradiated mucosa at a rate impossible to control Three of these tumors, the 2 of the tongue and the 1 of the anus, developed in patients treated for cancer of adjacent organs or tissues The anal lesion could hardly be a late localized recurrence of the cancer of the cervix treated 11 years before, the one epidermoid carcinoma of the tongue could not be a recurrence of malignant mixed tumor of the parotid, which showed no local persistence after 9 years The other tongue lesion occurred in an irradiated area 13 years after successful radiotherapy for a presumed cancer of the nasopharynx The 2 hypopharyngeal cancers occurred in patients treated for inflammatory cervical lesions, one of them tuberculous adenitis The squamous cell cancer of the buccal mucosa represents the culmination of a compound tragedy of errors in a patient whose ossifying fibroma of the upper maxilla was erroneously diagnosed as adamantinoma and treated with irradiation over a period of years Even if the tumor had been an adamantinoma the irradiation was incorrect treatment

In 3 patients adenocarcinoma developed An adenocarcinoma of the transverse colon developed directly beneath an obvious area of skin change on the anterior abdominal wall where irradiation had been used as treatment for a duodenal ulcer four years before The time interval is short as compared with the intervals in reports of other irradiation-induced cancers, but the previous treatment and residual objective findings at least suggest a causal connection The carcinoma of the rectosigmoid occurred in the field of irradiation in a woman treated for cancer of the uterine cervix Again the time interval is only three years, but there is demonstrable irradiation change in the intestinal wall about the tumor In the patient with the adenocarcinoma of the cervical esophagus the long interval between irradiation and tumor formation (25 years) and the obvious irradiation changes in the tissues of the neck indicate that this is almost certainly an irradiation-induced cancer The epithelium of mucous membranes, like that of the skin, is capable of malignant tumor formation as a late effect of irradiation

NEUROLOGY & PSYCHIATRY

Virologic Investigations on the Etiology of Two Institutional Epidemics of Poliomyelitis P Kraus Monatsschr Kinderh 105 17-19 (Jan) 1957 (In German) [Berlin]

One of the 2 poliomyelitis epidemics discussed in this paper occurred in an infant nursery, the other in a whooping cough pavilion in another children's hospital In the infants' nursery 10 strains of poliomyelitis virus, all of which belonged to the Brunhilde or type 1 virus, were cultured from 23 specimens of feces, This type of virus was isolated not only in the nursling, who seemed to be the carrier responsible for the epidemic outbreak, but also in 5 of the 8 infants in whom symptoms of poliomyelitis developed and in 1 of 5 who remained free from symptoms The epidemic character of this outbreak, which occurred in July and August, was proved not only by the presence of type 1 virus but also by the demonstration of neutralizing antibodies in nearly all the infants This, moreover, proved that the capacity of infants to form antibodies is not significantly less than that of adults Two of the 9 infants who had symptoms had the meningitic form of poliomyelitis, and all the others had paralytic signs

The epidemic in the whooping cough pavilion occurred in December, 1955 The paralytic form of poliomyelitis occurred in only 1 of 22 young children Spinal punctures were performed in all of these children and an increase in the cell count was observed in 10 of the remaining 21 Examination of the feces disclosed poliomyelitis strains of type 1 in 4 of these 10 children The same type of virus was found also in the feces of the child with paralytic poliomyelitis and in the feces of 1 of the 4 nurses Serologic tests were carried out in all of the children twice The comparison of spinal cell counts with the serologic tests indicated an increase in the titer, showing that infection had taken place in all but 3 of the children The fact that no serologic changes were detected in 5 despite an increase in the cerebrospinal fluid cell count is explained by technical inadequacies The contrary occurrence, that is, a serologic reaction without a spinal fluid reaction, which was observed in 3 patients, proves that a poliomyelitis viremia (the prerequisite of antibody formation) can occur without a pathological reaction in the central nervous system Despite the differences in the clinical manifestations of these 2 epidemics, they showed the characteristics that the authors had previously observed in infections with type 1 virus, namely, a tendency to cause epidemics in groups not immunized against poliomyelitis

Value of Pneumoencephalography and Other Methods of Examination in Diagnosis of Organic Brain Diseases Study of Clinical Material C L Laane, T Solheim and A Straand Tidsskr norske lægefor 77 107-112 (Feb 1) 1957 (In Norwegian) [Oslo]

Pneumoencephalography is helpful in evaluating the possible presence of organic brain changes Because of suspected brain disease suggested by clinical, electroencephalographic, and/or neurological findings, it was carried out in a series of 100 psychiatric patients and ive positive evidence of organic brain disease in 70 Most of the positive pneumoencephalographic results ere in patients aged 31 to 60 years with duration f illness of 1 to 10 years In 44 of 49 patients with linical signs of organic brain disease the pneumo- ncephalographic examination gave positive results he results were positive in 25 of 28 patients with ositive electroencephalographic findings and in 20 of 2 with positive neurological findings Roentgeno raphic examination of the head was of little value Besides pneumoencephalography, careful clinical ex- mination is the most valuable method for detecting rganic disease of the brain

Abnormal Immunological Reactions in Disseminated clerosis A Preliminary Report H V Smith M L E spir, C W M Whitty and W R Russell J Neurol eurosurg & Psychiat 20 1-10 (Feb) 1957 [London]

It has been established that the injection of tubercu- n into the spinal fluid of a sensitized subject evokes a ave of inflammation involving the meninges and to ome extent the vessels of the brain and spinal cord his is a true antibody-antigen response It exerts a rofound effect on the permeability of the blood-brain arrier, and it has proved a useful adjuvant in the reatment of tuberculous meningitis Because it was uggested to the authors that these reactions might be eneficial in multiple sclerosis, they studied the effects f the intrathecal injection of tuberculin in this disease nd compared them with the effects in psychosis of ixed etiology The different factors involved were xplained to the patients with multiple sclerosis, and olunteers were obtained Most of the patients had een under observation for months or years Serial Mantoux tests were done in the usual way with old uberculin, diluted to 1 in 10,000, 1 in 1,000, and 1 in 00 The purified protein derivative of tuberculin was sed for the intrathecal injections The mental dis- rders in the controls ranged from mental deficiency o advanced schizophrenia, and some had been sub- ected to cingulectomy and leukotomy In all of them he spinal fluid was normal at the first examination

Striking and consistent differences were observed between the intrathecal tuberculin reaction in the patients with multiple sclerosis and the controls In particular, the correlation seen in the controls between the intensity of the intrathecal reaction and the result of both the Mantoux test and the dose of tuberculin was not apparent in multiple sclerosis The pattern of the reaction also was distorted, in that the characteristic polymorphonuclear leukocyte component was suppressed, while the increase in protein was exaggerated A similar suppression of the polymorphonuclear component could be artificially produced in controls by giving cortisone The response in tuberculin-negative patients with multiple sclerosis to vaccination with Wells' vole vaccine or BCG was anomalous, in that, contrary to experience with the controls, sensitization of the skin and of the meninges was markedly dissociated The immediate clinical effects of the intrathecal injection of tuberculin were alarming in 2 patients with brain-stem lesions but otherwise were associated with little immediate change in the clinical findings Follow-up studies suggested, however, that the course of the illness may have been modified for good

Electroencephalogram in Narcolepsy D D Daly and R E Yoss Electroencephalog & Clin Neurophysiol 9 109 120 (Feb) 1957 [Montreal, Canada]

Narcolepsy is characterized by episodes of sleep usually of brief duration but recurring many times daily In many instances there are associated cataplectic attacks characterized by loss of muscle tone without change in consciousness These attacks are commonly induced by laughter, anger, fright, or startling stimuli Episodes of so-called sleep paralysis may occur while falling asleep or awakening During these the patient is conscious but unable to move Many patients with narcolepsy are also subject to hypnagogic hallucinations and nightmares The 100 patients reviewed in this article belong to a series of 241, in all of whom the diagnosis of narcolepsy had been established clinically This group of 100 patients in whom electroencephalographic studies were made did not differ in any essentials from the entire group of 241 patients The series was compiled by selecting consecutively the records of 100 patients from the files of the electroencephalographic laboratory during the years of 1950 to 1954 Sixty-four of the patients were men and 36 women Seventy-one were between 21 and 50 years of age The decade of age in which there was the largest number of patients was 31 to 40 years In 85 of the patients the narcolepsy was associated with other symptoms of cataplexy, sleep paralysis, or nightmares in varying combinations The most frequent combination, occurring in 37, was narcoleptic and cataplectic attacks

Recordings were made on 8-channel model IV Grass electroencephalographs A total of 14 electrodes was used No attempt was made to permit the patients to go to sleep during the routine recording The basal or alert electroencephalograms were found to be within normal limits Drowsiness began within the first 4 minutes of the recording in most patients Almost all patients manifested drowsiness at some time during the recording Sustained drowsiness lasting for periods up to 30 minutes was characteristic of these patients Opening and closing the eyes, counting, hyperventilation, and photic stimulation, measures which alert the normal patient were commonly ineffective in narcoleptics In spite of persistent drowsiness, actual sleep was uncommon under the circumstances in which the recordings were made Electroencephalograms made during cataplectic attacks and an attack of sleep paralysis were normal

Medical Aspects of Boxing, Particularly from a Neurological Standpoint M Critchley Brit M J 1 357-362 (Feb 16) 1957 [London]

The author has observed 69 patients with chronic neurological disease due to boxing Many of these showed evidences of punch-drunkenness, either early or well established Chronic progressive traumatic encephalopathy of boxers is suggested by the author as an alternative name for the popular term "punch-drunkenness." Punch-drunkenness is more frequent among professionals than among amateurs and among second-rate or third-rate performers than in the intelligent scientific exponent with a championship title. It is rare in Negroes. Punch-drunk states have been found in fighters of all weights, but most characteristically in small men who had not been particular about the size of their opponents, having often taken on contestants heavier than themselves. There is a correlation between the degree of craniofacial marking and the intensity of the punch-drunk syndrome. The total number of bouts is important, as well as the number of occasions on which the boxers have been rendered unconscious. As a rule, gradual evolution of mental and physical anomalies marks the insidious onset of the encephalopathy. Among mental symptoms there is the slow appearance of a fatuous or euphoric dementia with emotional lability. The victim shows little insight into his condition. Speech and thought become progressively slower, memory, efficiency, and conduct deteriorate, and there may be mood-swings, intense irritability, and sometimes truculence leading to uninhibited violent behavior. Simple fatuous cheerfulness is, however, the most prevailing mood, although sometimes there is depression with a paranoid coloring. The patient may complain of persistent dull headache, postural dizziness, deafness, poor vision, intolerance toward alcohol, unsteady gait, and shakiness. Occasionally periodic convulsions bring the victim to the doctor.

The condition popularly referred to as a "groggy state" is the result of severe battering sustained during a particular contest. The victim develops a mental confusion with subsequent amnesia, and an impairment in the speed and accuracy of his motor skill. In this state he makes feeble and poorly coordinated movements, his limbs are ataxic, and he is inefficient and vulnerable. An accumulation of groggy states probably leads to a permanent punch-drunk syndrome. Remitting cerebral concussion is suggested as an alternative term for groggy state. Minor nonspecific anomalies are common in the encephalogram of experienced boxers. Such findings are more frequent and more intense in those with punch-drunkenness. The electroencephalogram is a less sensitive index of punch-drunkenness than is the clinical evidence, for symptoms and signs may be present at a time when the electroencephalogram appears to be normal. A return to a normal state in a series of electroencephalograms taken in a particular patient cannot be regarded as a physiological, anatomic, or clinical recovery.

Brain Abscess and Cerebral Venous Thrombosis Associated with Congenital Cardiac Defects. G. Weber. Schweiz. med. Wchnschr. 87:159-163 (Feb. 16) 1957 (In German) [Basel, Switzerland]

Of 79 consecutive patients with brain abscess, 4 had congenital cardiac defects. Of the 4 patients, the 1st, a 13-year-old boy, with pulmonary stenosis and transposition of the aorta, had a chronic sterile abscess in the lateral posterior segment of the right frontal lobe. The encapsulated abscess was extirpated from the subcortical medullary layer of the frontal lobe, and complete recovery resulted. The 2nd patient, a 24-year-old man with transposition of the aorta and with atrioventricular septal defect, had an acute nonencapsulated abscess in the lateral posterior segment of the right frontal lobe which was punctured and drained through a trephine opening in the right lateral portion of the frontal lobe. Antibiotic treatment was practiced with large doses of penicillin, streptomycin, and sulfonamides, and complete recovery resulted. The 3rd patient, a 25-year-old woman whose heart had 1 atrium and 2 ventricles, also had hypoplasia of the right ventricle, high ventricular septal defect, subtotal auricular septal defect, atresia of the tricuspid valve, transposition of the aorta, and pulmonary stenosis, an abscess located in the left temporal lobe was found to be associated with a large internal pyocephalus, which caused central respiratory paralysis and death. The 4th patient, an 8½-year-old boy whose heart had 1 atrium and 2 ventricles and atresia of the tricuspid valve, had an acute frontoparietal brain abscess associated with a craniopharyngioma, death resulted from respiratory paralysis. A 5th patient, an 11-month-old girl with Fallot's tetralogy, had thrombosis of the superior sagittal sinus and the cerebropontine veins. Death resulted from hemorrhagic infarction of both cerebral hemispheres.

Brain abscess and thrombosis of cerebral vessels may occur as complications in patients predominantly aged less than 30 years with congenital cardiac defects. A brain abscess may be associated with a congenital heart defect with intracardiac admixture of venous with arterial blood, and, therefore, most frequently with tetralogy of Fallot. The occurrence of a brain abscess is favored by a compensatory polyglobulism, which causes increased viscosity of the blood, slows the peripheral blood flow and so probably favors thrombosis. The source of infection frequently remains unknown in patients with such a brain abscess. It may be located in the area of either the greater or the lesser circulation. Brain abscesses associated with congenital cardiac defects are, as a rule, amenable to treatment.

GYNECOLOGY & OBSTETRICS

The Effect of Hysterectomy on Young Women. W. M. Jacobs, H. I. Daily and S. H. Wills. Surg. Gynec. & Obstet. 104:307-309 (March) 1957 [Chicago]

Of a series of 568 hysterectomies, 68 (12.1%) were performed on women under 30. Forty-six of the 68 could be interviewed from 1 to 2½ years after the hysterectomy, and the following questions were asked: 1. Do you feel that your operation was worth while, and are your symptoms relieved? 2. Has the operation affected your sexual life? 3. Are you concerned about having no future menstrual periods? 4. Are you concerned that you will not be able to become pregnant? 5. Do you have any hot flushes or extreme nervousness, and, if so, do you take any treatment for these symptoms? All but 4 of the 46 patients were completely relieved of their symptoms, 3 were partially relieved, and 1 patient stated that she had not been helped by the operation Regarding the effect on sexual relations 28 said that there was no change, 13 who had had dyspareunia before operation were relieved of this and now had greater sexual satisfaction, and 5 reported that sexual relations were slightly less satisfactory, but they were not unduly concerned None expressed concern over the loss of menstrual function Only 2 of the 46 patients worried about the loss of fertility Twenty-seven patients reported no vasomotor symptoms and 19 reported mild to moderate symptoms, quickly relieved by mild sedation

The authors conclude that the more complete type of hysterectomy provides much better results than does partial resection, leaving behind a nonfunctioning uterus simply because a patient happens to be relatively young If the pelvic disease has made future pregnancies impossible, a total hysterectomy should be performed, provided the patient is in good physical condition and has been made aware of the procedure and agrees to it beforehand

A Study of Bladder Function Following Vaginal Hysterectomy J W Bowers, C W Moeckel, G L Yates and H R Wesson Surg Gynec & Obst 104 287-294 (March) 1957 [Chicago]

Cystoscopic, cystographic, and manometric studies were performed in 15 patients treated by vaginal hysterectomy and repair The patients were unselected except that, in 8, postoperative urethral catheter drainage was carried out and, in 7, postoperative trocar cystotomy drainage Observations on these 15 patients indicate that after temporary postoperative atony of the detrusor the voiding contraction approaches preoperative levels by the 5th to 7th days Postoperative bladder capacity is always less than before surgery Spastic bladder phenomena are frequently associated with retention and residual urine Postoperative urinary retention and associated voiding difficulties are most closely related to vesical neck obstruction, i e , surgical overcorrection, urethral edema, and sphincter spasm

In 100 of 200 vaginal hysterectomies indwellling urethral catheter drainage was carried out postoperatively and in the other 100 vaginal hysterectomies diversion of the urinary stream by means of trocar cystotomy was performed in the operating room It was found that trocar cystotomy, as a form of temparary bladder drainage, is associated with a slight increase in morbidity, prolongation of initiation of voiding and of hospital stay postoperatively, increase in residual urine on discharge, and increase in frequency of late postoperative bladder symptoms Direct complications of trocar cystotomy were bladder calculi (7 cases), hematuria (4 cases), and late rupture of bladder (1 case) Bladder calculi have recently been prevented by weak acid irrigations postoperatively Trocar cystotomy drainage has the advantages of requiring less nursing care and increasing the patient s comfort Trocar cystotomy drainage appears to be a valuable adjunct in the management of bladder dysfunction following vaginal hysterectomy, routinely or in selected cases in which a prolonged period of urinary retention is anticipated General anesthesia was followed by a 20% higher morbidity than spinal anesthesia in the entire series of 200 cases Trocar cystotomy appeared to circumvent the postoperative urethritis which is so often a distressing sequel to indwelling urethral catheter drainage

Diagnostic Value of Puncture of Rectouterine Excavation (Douglas' Pouch) in Intra abdominal Hemorrhage Caused by Extrauterine Pregnancy E Hermann Zentralbl Gynak 78 700-706 (No 18) 1956 (In German) [Leipzig, Germany]

At the hospital with which this author is connected, puncture of the rectouterine excavation has been used systematically for more than 2 decades, particularly for the differentiation of complications caused by extrauterine pregnancies from inflammatory gynecologic disorders Puncture of the rectouterine excavation is of particular value because it reduces the number of exploratory laparotomies, and at the author's clinic an operation for a suspected ectopic pregnancy is almost never carried out without a diagnostic puncture of the rectouterine excavation Exceptions to this rule are cases in which an ectopic pregnancy is either not suspected or a tubal rupture is clearly evident The author believes that a diagnosis of a ruptured tubal pregnancy is made if puncture yields not only a relatively large quantity of blood but particularly if clots are present The aspiration of a large quantity of blood always indicates a threatening condition, but the aspiration of only a small quantity, or a negative aspiration, does not necessarily rule out an extrauterine pregnancy If the clinical findings are suggestive then the operation is performed even if the puncture yields no blood, otherwise the patient is carefully observed for 24 hours and then the puncture is repeated The author does not resort to irrigation of the rectouterine excavation

A total of 313 patients with suspected ectopic pregnancy were admitted to the author s clinic in the decade between 1946 and 1955, in some the suspicion of an ectopic pregnancy being raised only after admission The diagnosis of an extrauterine pregnancy could be excluded in 20 of these patients on the basis of a thorough general and gynecologic examination A puncture of the rectouterine excavation was done in 290 of the remaining 293 In 179 the puncture gave a positive result, an operation was performed in 176, and the extrauterine pregnancy was found in 164 of these women Of the 3 not operated on 1 died during the examination as the result of hemorrhage, the other 2 were not operated on because the gynecologic examination did not indicate an extrauterine pregnancy despite the presence of blood in the rectouterine excavation Tubal pregnancy was found in 162 (26 tubal ruptures and 136 tubal abortions) and omental pregnancies in 2 women The 12 patients in whom the operation did not disclose an extrauterine pregnancy included 5 with a ruptured corpus luteum cyst, 2 with a ruptured follicular cyst, 1 with tubal tuberculosis, 1 with a uterine perforation resulting from curettage, and 1 with a perforated duodenal ulcer, in the remaining 2 the origin of the hemorrhage could not be ascertained In 111 of the 290 patients puncture of the rectouterine excavation gave a negative result

PEDIATRICS

Vaccinations Against Smallpox in Very Young Children H J Doorschodt Maandschr kindergeneesk 25 1-8 (Jan) 1957 (In Dutch) [Leyden, Netherlands]

The author comments on the complications of smallpox vaccination, giving particular attention to postvacinal encephalitis Changes in the regulations on vaccinations in the Netherlands have provided an opportunity to shed more light on the incidence of this serious complication Evidence was obtained that it was much less frequent when the primary vaccination was carried out in children less than 2 years old than in older children The aim of the studies presented here was to investigate whether smallpox vaccination could be successfully carried out at a very early age, that is, during the first 3 months of life Studies were made on over 1,000 infants between 6 weeks and 1 year old The efficacy of vaccination was ascertained by determining the antihemagglutinin and virus-neutralizing antibodies in the serum of the vaccinated child 3 weeks after the inoculation with smallpox vaccine

It was found that the amount of antibodies present in infants less than 3 months old was on the average only slightly lower than in older children The author concludes that if vaccination is performed carefully it is as successful in infants of less than 3 months than in older children Furthermore, the vaccination of young infants has a number of advantages over that in older children 1 The young child does not appear sick after vaccination, and this fact reduces the opposition of the public to vaccination 2 The fact that the young child is alone in his cradle reduces the danger of spreading complications caused by the vaccine 3 The danger of the postvaccinal encephalitis is very slight at this early age 4 Contraindications such as the existence of eczema or exposure to acute infections is likewise less than later 5 If smallpox vaccination is complete at 4 months of age, immunization against whooping cough, diphtheria, and tetanus can be begun

Heat Regulation of the Premature Infant in Climatized Incubators Improvement of Thermal Insulation of Incubators with Plexiglas Hoods J Gleiss Ztschr Kinderh 79 147-157 (No 2) 1957 (In German) [Berlin]

The following questions were investigated 1 Do the rhythmical temperature fluctuations of climatized incubators with warm-air blowers influence the thermoregulation of permature infants? 2 How do the thermoregulating mechanisms of the incubator and the infant within it react to rapid changes in the surrounding room temperature? The dependence of the thermal regulation of the premature infant on that of the incubator becomes most clearly evident in the behavior of the infant s "internal" temperature (measured in stomach or rectum) Measurements demonstrated that the thermoregulation of premature infants is influenced by the rhythmical temperature fluctuation of incubators The "internal" temperature of a premature infant reacts the more readily the more premature the child is Changes in room temperature amounting to several degrees (Centigrade) influence the temperature in the incubator and with this that of the infant, in that the infant's "internal" temperature changes in the same direction (up or down) as does the room temperature

It was found that inadequate insulation of the incubator hood is the essential cause of thermoability of the incubator and of the infant within it In order to improve the thermal insulation of the incubators heated by warm air currents, it is suggested that an air-jacket be created by inserting a thin-walled plexiglas layer within the outer hood To further reduce the thermal disturbances in closed incubators heated by warm air currents it is suggested that the opening admitting the warm air should be at the foot end rather than at the head end The physician is responsible for any harm that a premature infant may sustain in an incubator For this reason he must inform himself about the construction and the mode of operation of incubators so that injurious effects will be avoided

Intrauterine Forms of Breathing K Dietel and V Dietel Ztschr Kinderh 79 203-210 (No 2) 1957 (In German) [Berlin]

The term "maturation of the respiratory center, implies that lower forms of breathing (gasping and periodic breathing) become replaced by the normal rhythm of breathing The more immature the fetus or child the greater is the tendency to lower forms of breathing Gasping or snapping respiration, for instance, has been observed in fetuses delivered during the 4th month of gestation Hiccup is a special form of snapping respiration, in which the diaphragm is lowered so the air is inspired in jerks Periodic breathing of the Cheyne-Stokes type is most frequent during immaturity The respiratory center in the medulla oblongata is an ontogenetic unit in which the lower centers such as those for the gasping or snapping form of breathing or for periodic breathing are being superseded or replaced by higher centers governing the normal rhythm of breathing During the process of dying the ontogenetic processes in the composite respiratory center are reversed, in that the normal respiratory rhythm is replaced by periodic and this again by gasping respiration The authors are concerned with the question as to what forms of respiration can be observed in the fetus in utero Rhythmical, gliding, and wave-like movements can be observed in the region of the maternal umbilicus as pregnancy draws to the end They are strongest in cases in which the chest of the fetus lies against the anterior wall of the uterus The intrauterine respiratory movements can be seen, felt, or registered with Marey's capsule through the maternal abdominal wall

In the investigations carried out by these authors the forms of respirations of the fetus in utero were compared with those observed in premature infants The palpating hand differentiated between respiratory and body movements Most of the tests were made at the end of pregnancy Normal respiratory rhythm was observed most frequently It generally continued for 2 to 5 minutes The longest period during which the authors were able to register it was 13 minutes, then the fetal chest turned somewhat, so that no further movements could be observed The normal rhythm is interrupted by periods of arrest of varying length, but averaging 20 or 30 seconds The longest intrauterine apnea lasted 2 minutes Periodic breathing such as is observed in immature premature infants is characterized also in the fetus in utero by gradual decrease in the depth of breathing followed by respiratory arrest Alternating changes between normal and periodic rhythm are frequent in utero Pure hiccup was observed in one case 2 days before delivery, but otherwise this type of respiration is more frequent during the middle than toward the end of pregnancy Why do forms of respiration occur before birth that occur only in the immature and during the decay of the respiratory center? In the fetus in utero the higher respiratory centers may interrupt their function This also interrupts the inhibitions which are exerted by these centers on the lower centers Thus lower forms of respiration may appear Two different respiratory rhythms may show relative coordination in utero Certain stimuli modify the automatism of the higher centers temporarily

Conduct Disorders in Epileptic Children F Grunberg and D A Pond J Neurol Neurosurg & Psychiat 20 65 68 (Feb) 1957 [London]

Fifty-three epileptic children with behavior disorders were compared with 53 psychiatrically normal epileptic children in respect to organic, genetic, and social environmental factors The 2 groups differed significantly as to their social environment The epileptic children with behavior disorders had a more disturbed family background The most significant social environmental factors were a disturbed emotional maternal attitude towards the child and experiences by the child of breaks and changes in environment When 35 epileptic children with behavior disorders were compared with 35 nonepileptic children with the same behavior problems, the same adverse social environmental factors were found in both groups The disturbed family background associated with conduct disorders in childhood epilepsy, whether causal or not, must be dealt with by combined medical and child-guidance techniques

DERMATOLOGY

Rhythms in the Biologic Process in Normal and Abnormal Nails A Stuhmer Arch klin exp Derm 204 1-12 (No 1) 1957 (In German) [Berlin]

In some patients with psoriasis rows of small pits arranged chain-like along the longitudinal ribs of the nail were observed The development of these rows of pits suggests a periodicity in the process of psoriasis The stimulus apparently acts on the proximal end of the nail matrix for only 2 or 3 days at a time Then the nail growth is normal again, but after an interval of 28 or 30 days the stimulus that produces the pits recurs Uninterrupted chains of these pits can be observed from the nail bed to the anterior rim of the nail In patients with diffuse scleroderma, roof-shingle-like markings could be seen on the surface of the nails These same changes, although somewhat less pronounced, were observed also on the nails of patients with psoriasis and on the nails of elderly persons without skin lesions The author designates these structural changes in the nails as shingle-like onychodystrophy, and emphasizes that they suggest rhythmical changes in the growth of the nails

Treatment of Tuberculosis of the Skin According to Statistics of 369 Treated Cases from 1941 to 1956 C Huriez and P H Pelce Semaine hôp Paris 33 571-580 (Feb 14) 1957 (In French) [Paris]

A series of 369 patients with tuberculosis of the skin were treated during the last 15 years in the most phthisiogenic region of northern France Lupus vulgaris was cured in 55% of the patients by a rotating treatment with antibiotics and calciferol Isoniazid combined with streptomycin and calciferol resulted in the cure of all varieties of tuberculous lupus Thanks to isoniazid, the healing rates of patients with tuberculosis of the skin, who scarcely responded to vitamins, improved greatly 80% of those with initial lesions 100% of those with verrucous forms, 75% of those with vegetative ulcers, and only 55% of those with scrofuloderma were healed, although isoniazid had been injected in situ The necessity of a combined antibiosis with isoniazid as the essential element, of a prolonged use of the antibiotics for at least 1 year, and of complementary therapy with vitamin D_2 is emphasized Further experiments showed a 'cortisone-like' action of large doses of vitamin D_2 Good results were obtained in 20 patients, particularly in 6 with scrofuloderma, by corticotherapy combined with antibiotics This treatment cannot be generally applied because of the risk of tuberculosis It should be used only in patients, who do not respond to treatment with antibiotics and vitamins An increase of the isoniazid level, after cortisone was given, was observed in a study of isoniazid metabolism, made in 250 blood tests This proved the potentiating action of cortisone The histological changes during treatment with antibiotics resulted in collagenous sclerosis, which is the final stage common to all healing processes The authors emphasize the rotating therapy of antibiotics and vitamin D_2 The general trend in the treatment of infectious lesions is to combine specific with nonspecific agents

OTOLARYNGOLOGY

Antibiotic Deafness O Popper South African M J 31 54-56 (Jan 19) 1957 [Cape Town, South Africa]

The author reports on 93 patients with antibiotic deafness Wide incisions of the posterior quadrant of the ear drum were made The discharge was tenacious and viscid in 1 patient, in whom fluid in the middle ear had persisted for months, and the author had to incise 5 times Incision was made three times in 7 and twice in 17 patients This treatment was insufficient for 18 patients Drainage of the attic and antrum tympanicum cleared the condition of these patients completely The method used was an endaural transtympanic atticoantrostomy An acute otitis media is not necessarily cured by the administration of antibiotics Antibiotic deafness is due to the retention of fluid in the middle ear after acute otitis media treated with antibiotics Conductive deafness may be caused by the large doses of antibiotics, which act rapidly (within 24 hours), arresting inflammation The retained fluid becomes sterile and the capillaries are not stimulated to dilate and absorb this fluid This is likely to become reinfected The infection may be latent in the attic and antrum Treatment should be as conservative as possible It varies from simple incision to more extensive measure

Bronchogenic Carcinoma Diagnostic Aspects of 228 Proved Cases C H Steele Laryngoscope 67 137-146 (Feb) 1957 [St Louis]

Of 228 patients between the ages of 31 and 80 years with proved bronchogenic carcinoma, 200 were men and 28 were women The diagnosis was established by biopsy exploration, or autopsy A positive diagnosis was made by bronchoscopic biopsy in 92 (40 4%) Two hundred four (89 9%) of the 228 patients smoked, 150 (65 7%) smoked 20 or more cigarettes daily, or an equivalent amount of pipe or cigar tobacco, for periods ranging from 20 to 45 years Two hundred three patients (89%) were city dwellers and lived in an environment in which the atmosphere contained varying amounts of possible carcinogenic dusts, gasses, fumes, and chemicals Sixty-five per cent of the group worked indoors, and 35% worked predominantly outdoors Examination of operative or autopsy specimens revealed squamous cell carcinoma in 103, undifferentiated carcinoma in 77, and adenocarcinoma in 48 While only a small percentage of the epidermoid and undifferentiated carcinomas occurred in women, a more nearly equal distribution was found in adenocarcinoma

The cardinal symptoms of bronchogenic carcinoma in order of frequency were cough, lingering respiratory symptoms after influenza, chest cold or pneumonia, chest discomfort or pain, dyspnea, and hemoptysis The average duration of symptoms from onset to positive diagnosis was 7 6 months The average delay from the first medical consultation to positive diagnosis was 3 1 months Signs of endobronchial obstructions were the most common physical signs Roentgenograms of the chest proved to be the most valuable single means of obtaining a presumptive diagnosis of pulmonary cancer Two hundred twenty-one patients (97%) were suspected by the roentgenologist to have *bronchogenic carcinoma* Bronchoscopy was of value in establishing the diagnosis of bronchogenic carcinoma by visualization and biopsy of the lesion and by permitting bronchial lavage of selected areas of the pulmonary tree for cytological examination Bronchoscopy was also an aid in determining operability based on the presence or absence of anatomic-pathological changes in the tracheobronchial tree suggestive of bronchogenic carcinoma

Cytological study of bronchial aspirate specimens, after bronchial lavage, was done in 61 patients The presence of malignant cells was noted in those obtained from 29 (47 5%) of the 61 patients A high percentage of bronchial aspirates containing malignant cells was revealed by the cytological study of specimens obtained by abrasion of the bronchial wall with bronchoscopic forceps or aspirator followed by forceful washing of such areas with sodium chloride solution With increased experience, a positive diagnosis of bronchogenic carcinoma was made by cytological examination of bronchoscopically recovered secretions in 55 5%, while such a diagnosis was made with the aid of forceps biopsy in 25 9%

Intubation Granuloma S S Epstein and P Winston J Laryng & Otol 71 37-48 (Jan) 1957 [London]

Intubation granuloma is a complication of endotracheal anesthesia that is becoming more frequent due to the increasing use of intubation There is no doubt that the condition is far more common than the 55 cases collected from the literature would indicate The data on these 55 cases are tabulated and the authors present findings on 10 additional cases observed in a London hospital between 1948 and 1956 A few of these patients were referred to the staff of this hospital following operation elsewhere Six of the 10 patients had unilateral and 4 had bilateral lesions Hoarseness is the presenting symptom in most patients Respiratory obstruction may occur if the granuloma is large and especially if bilateral Emergency removal may be necessitated on this account The diagnosis is easily made in a patient who complains of persistent postoperative hoarseness Intubation under direct vision with the smallest possible tube, use of muscular relaxants, avoidance of too light a plane of anesthesia during induction, and prevention of excessive flexion of the neck during operation have been suggested as prophylactic measures, but the authors regard their value as debatable They believe that the Magill tube by virtue of its shape and resilience must be held responsible for pressure necrosis in the region of the posterior commissure and occasionally on the anterior tracheal wall Dwyer strongly recommended a tube curved in two planes to achieve greater conformity with the natural shape of the air passages

As intubation granuloma originates from an abrasion of the vocal process, there is little doubt that early recognition of postintubation laryngeal damage will minimize the risk of subsequent granuloma formation Hoarseness persisting more than 2 days after an operation in which intubation was performed is a clear indication for laryngoscopy Should there be any ulceration of the vocal process, absolute vocal rest until complete healing occurs is probably the most important single factor in the prevention of intubation granuloma *Removal of a sessile intubation granuloma* exposes a large bare area which will gradually heal by granulation, possibly with recurrence of granuloma formation

The Clinical Significance of the Ramification of the Recurrent Laryngeal Nerves A Critical Anatomical Study H Pichler and A Gisel Laryngoscope 67 105 117 (Feb) 1957 [St Louis]

In 1948, King and Gregg studied the reasons for the various behaviors of the vocal cords after partial or total paralysis of the recurrent laryngeal nerves occur-ing after thyroidectomies and other operations of the throat or after traumas of the neck These American workers emphasized the clinical significance of an extralaryngeal division of the recurrent laryngeal nerve into anterior and posterior branches, which according to their statement 'offers the only rational explanation of all lower motor neuron vocal cord paralyses' King and Gregg's report induced a series of studies carried out by the authors at the Anatomical Institute in Vienna One hundred dissected recurrent laryngeal nerves were prepared, 40 preparations were made in situ, and later 60 were done on isolated larynges Extralaryngeal divisions were found in all of the 100 nerve preparations on microscopic examination The extralaryngeal division of the recurrent nerve was identified as a division in motor and sensory fibers It occurred at the level of the first, second, or third tracheal cartilage At the point of the bifurcation the recurrent nerve gave off a sensory branch which was distributed to the mucosa of the hypopharynx, then split and subdivided, forming an anastomosis between the inferior and superior laryngeal nerves It thus constituted the caudal portion of Galen's loop

This nerve was located on the cricoarytenoideus posterior muscle In every instance, the ramus posterior proper branched off only endolaryngeally The division of the inferior laryngeal nerve into the posterior ramus (the mesial branch) and the anterior ramus (the lateral branch) occurred in all cases about 1 cm above the lower edge of the cricoid cartilage The ramus posterior proper was located below the cricoarytenoideus posterior muscle, between the muscle and the perichondrium The authors could not trace any low extralaryngeal division of the recurrent nerve into abductor and adductor branches, respectively, but the presence of this anatomic condition constitutes an essential requirement of the King-Gregg hypothesis Since most workers express serious doubts concerning the motor innervation of Galen's loop, one must caution against overrating the clinical importance attributed to the presence of an extralaryngeal motor ramus posterior to the recurrent nerve There are serious reasons to doubt that the problem of the baffling behaviors of the vocal cords after thyroidectomy has as yet been satisfactorily solved by the explanation offered by King and Gregg

PATHOLOGY

Statistical Findings and Considerations on Tumors Observed Between 1945 and 1954 P Aresu Rass med sarda 58 33-53 (Jan -Feb) 1956 (In Italian) [Cagliari, Italy]

In 1,914 autopsies performed between 1945 and 1954, 171 tumors were found, of which 26 were benign and 145 malignant Benign tumors were most frequent among patients 40 to 50 years old and malignant tumors among patients 40 to 70 years old and especially among patients in the 60 s The connective tissue and the urogenital apparatus were the most frequent location for benign tumors, the greatest number of malignant tumors were of epithelial origin and occurred most frequently in the digestive tract, followed by the urogenital tract, respiratory tract, and the lymphatic system Most of the benign urogenital tumors were fibromas of the uterus, these were followed by fibroadenomas of the breast The order of frequency in the location of the malignant tumors of the digestive tract was the liver (mainly cancrocirrhosis), stomach, bile ductus, pancreas, rectum, small intestine, palate, tongue, and esophagus Malignant tumors of the urogenital apparatus were located most frequently in the kidney and the uterus, followed by the bladder, prostate, and ovary Almost all tumors of the nervous system were gliomas and were mainly found in the cerebellum and in the frontal and parietal cerebral lobes All the malignant tumors of the respiratory tract occurred in the lungs except for 1 in the pleura and 1 in the larynx The tumors of the skeleton and of the lymphatic apparatus were all of mesenchymal origin

Analysis of the findings in specimens from 5,433 biopsies performed in the same decade revealed the presence of tumor in 2,184, of which 1,509 were malignant and 675 benign Malignant tumors were most frequent among patients 40 to 70 years old More specimens, both malignant and benign, were from women than from men The location in order of frequency for benign tumors was the urogenital tract, breasts, digestive tract, skin, nervous system, and respiratory tract, for malignant tumors it was the urogenital tract (427), digestive tract (382), respiratory tract (131), lymphatic system (113), skin (98), skeleton (46), sensory organs (39), endocrine glands (14), muscles (7), nervous system (5), and the hemopoietic organs (1) The origin of 335 tumors, 89 benign and 246 malignant, could not be established

The Clinical Value of Urinary 17-Ketogenic Steroid Determinations M J Levell, F L Mitchell, C G Paine and A Jordan J Clin Path 10 72-79 (Feb) 1957 [London]

The normal range of urinary 17-ketogenic steroids was established from assays on 182 persons ranging in age from 3 to 101 years The values show a rise during childhood, boys and girls having apparently identical ranges up to the age of 15 years, after which the level in boys rises to a higher average than that in girls Between the ages of 20 and 40 years the geometric mean for men, 12 mg per day, is significantly higher than that for women, 9 3 mg per day At any age the values for either sex seem to be better represented by a log-normal distribution than by a normal one, and for this reason the geometric means are given In later life the excretion of 17-ketogenic steroids in men appears to decline The values for women do not show a similar decline

The authors also present the values found in the following conditions adrenal cortical hypofunction, myxedema, hypopituitarism, pituitary basophilism, the adrenogenital syndrome, hirsuties, diabetes, thyrotoxicosis, amenorrhea, rheumatoid arthritis, and obesity The normal values observed in some patients with adrenal cortical hypofunction and pituitary basophilism and the unexpectedly high values found for adrenal steroids in some patients with pituitary insufficiency illustrate clearly the dangers of placing too much reliance on single determinations The limits of the normal range are wide, so that a person's 17-ketogenic steroid excretion may vary greatly without reaching a value which would be regarded as abnormal. In this respect, the status of the 17-ketogenic steroid assay is similar to that of the 17-ketosteroid estimation. These observations emphasize the desirability of performing an adrenal function test wherever indicated. The high values found in the patients with virilizing adrenal hyperplasias suggest a block in the biosynthesis of 17-hydroxycorticosterone with consequent overproduction of the precursor, 17-hydroxyprogesterone. As this substance does not adequately suppress the pituitary production of corticotropin, the effect is to produce adrenal hyperplasia and, although 17-hydroxyprogesterone is not in itself ketogenic, it is probably converted in part to a 17-ketogenic steroid.

The potentialities of the 17-ketogenic steroid assay in diagnosis and control of treatment are best studied by comparison with the 17-ketosteroid assay. In most of the conditions considered, as far as single estimations are concerned, the two methods yield about the same amount of information as judged by the extent of the departure from normal. In patients suspected of having the adrenogenital syndrome it is advantageous to have both assays performed, but in general it would seem that one would suffice. In view of the undoubted advantage of the 17-ketogenic steroid assay in following changes in adrenal function, as evidenced by corticotropin tests, by treatment of patients with hypothyroidism, and by response to stress, this is the assay of choice.

INDUSTRIAL MEDICINE

The Treatment of Tetraethyl Lead Poisoning. R. R. Boyd, G. Walker and I. N. Henderson. Lancet 1:181-185 (Jan. 26) 1957 [London].

Tetraethyl lead is a highly toxic liquid that is blended with gasoline. This organometal compound is absorbed through the skin and the respiratory and alimentary mucosa. It is probably distributed in a nonionic form, and, being lipid-soluble, it is concentrated in the brain, body fat, and liver. Its toxicity is due to its lead content, and, because of selective uptake, manifestations of poisoning are dominated by involvement of the central nervous system and differ from those of inorganic lead poisoning. Although the inhalation of tetraethyl-lead vapor for a brief period may be fatal, the continued excretion of large amounts of lead in the urine for some time after the removal of symptomless workers from prolonged minor exposure suggests that appreciable quantities of tetraethyl lead may be absorbed and the lead stored in a relatively nontoxic form. Three moderately severe cases of poisoning are described in this report, and a 4th case with a severe psychosis is mentioned. These 4 cases involved men who worked for 6 weeks cleaning underground tanks that had contained leaded gasoline. The affected men scraped the deposit containing tetraethyl lead from the floors and sides of the tank and shovelled it into buckets, which were hauled to the surface and emptied into pits. They were provided with protective clothing and equipment, but they neglected to adhere strictly to the prescribed precautions. During the period in hospital, urine was collected daily for estimation of lead, coproporphyrin and creatinine. In addition lead analysis was performed on daily fecal samples and on blood samples taken frequently.

Three of the patients were treated in turn for 3-day periods with edathamil calcium disodium in doses of 1 Gm. per 30 pounds of body weight per day, given intravenous drip lasting 4 to 6 hours, with 300 mg. of penicillamine 3 times a day by mouth and with 1 Gm. of edathamil calcium disodium by mouth 4 times a day. Intervals of several days were allowed between the different forms of treatment, and each treatment was preceded by 2 control days during which urine, feces, and blood were collected for analysis. The men were confined to bed for the first few days and received amobarbital as a sedative. A high fluid intake and full diet were encouraged. After discharge from the hospital, examinations and analyses were carried out at weekly intervals. Edathamil calcium disodium was given in 1 Gm. doses 4 times a day by mouth for alternate weeks until the clinical condition was satisfactory and the lead excretion normal. They, then took up work that did not involve exposure to toxic hazards.

Edathamil calcium disodium is the monocalcium disodium complex of ethylene diamine tetra-acetic acid. It is a chelating agent that combines with metallic ions forming nonionized, biologically inactive compounds. It has revolutionized the treatment of lead poisoning. Penicillamine (ββ dimethyl cysteine) like dimercaprol contains 2 thiol (-SH) groups per molecule. It increases the urinary excretion of copper in normal subjects and in patients with hepatolenticular degeneration as effectively as does dimercaprol. It was used in these patients to increase lead excretion, but it had little effect in this respect. While the urinary lead excretion was increased sevenfold by the intravenous injection of edathamil calcium disodium, it was influenced little by the oral administration of this drug or of penicillamine. The 4th patient, who had mania, hallucinations, and delusion, responded favorably to electroconvulsion therapy.

Delayed Death Caused by Gassing in a Silo Containing Green Forage. F. M. Troisi. Brit. J. Indust. Med. 14:56-58 (Jan.) 1957 [London].

A youth of 18 years of age and a boy of 12 descended into a silo on a small farm in Italy. The silo was of cement, cylindrical in shape, 6 meters (19 ft.) high and about 4.5 meters (14 ft.) in diameter, and about half its height was buried in the ground, with only one opening in the roof, which was closed with a metallic cover. Green forage, mixed with beans, barley, and oats had been preserved in the silo, which had been nearly empty for about a month, with the cover in place. The 2 youths entered the silo to remove the remaining silage. Shortly after reaching the bottom of the silo they became unconscious. A man of 61 standing nearby went into the silo to help them, and he also lost consciousness. All 3 were dragged out, and artificial respiration was applied. The 2 youths were already dead. The man was immediately taken to the nearest clinic. He appeared to be in extremis, the only sign of life was intermittent cardiac contractions. Artificial respiration was started at once, and cardiac and respiratory stimulants were given together with 500 ml of plasma intravenously After about an hour a few spontaneous respirations began, and in about 10 minutes tachypnea developed Consciousness was not regained at any time After 5 hours he was admitted to hospital completely unconscious This man died on the 5th day, despite the administration of oxygen, respiratory stimulants, and repeated blood transfusions preceded by bleeding The clinical findings were those of asphyxia with delayed death due to carbon dioxide intoxication and perhaps to anoxemia also

It should be remembered that carbon dioxide may accumulate in silos, whether they contain forage or grain The type of silo described above, half-buried in the ground and with a single opening in the roof, should be prohibited All silos should be provided with a free opening at the base Underground tanks and vats must be actively ventilated before they are entered, and the person entering such a chamber must be secured by a rope and be observed from outside When it is necessary to enter a chamber where the presence of carbon dioxide is known or suspected, it is essential to use breathing apparatus that draws air from outside the chamber Posters may be displayed at farms indicating the dangers and the necessary preventive measures Methods for testing enclosed atmospheres for the presence of carbon dioxide and sufficient oxygen are to lower lighted candles or small caged animals into the chamber

Decompression Sickness During the Sinking of a Caisson A Study of Some Factors in the Pathogenesis of Caisson Disease H E Lewis and W D M Paton Brit J Indust Med 14 5-12 (Jan) 1957 [London]

Most of the studies of decompression sickness have been made during the construction of tunnels The sinking of a caisson, however, involves certain special features not encountered in tunnel work This paper describes an investigation into the incidence of decompression sickness during the sinking of reinforced concrete caissons In the period during which the pressure exceeded 18 lb per sq in , there were 79 cases of bends affecting 37 men in a total number of 1,800 compressions at the inlet caisson At the outlet caisson there were another 10 cases in 310 decompressions This gives a total incidence of about 4% The incidence of bends began to rise when the pressure exceeded 20 lb , then rose to a high level for a brief period, and tended to fall thereafter even though the pressure was maintained This almost "epidemic' character of decompression sickness is a very common feature Bends consisted of aching pains most commonly affecting the joints The legs were the most frequently affected and next the arms The knees, wrists, shoulders, head, and the body in general were also affected A few workers were repeatedly victims of mild bends, and 2 had as many as 6 attacks each

Among the contributory factors to what was a rather high rate of decompression sickness were (1) inaccuracy in following the prescribed decompression procedure, (2) accumulation of carbon dioxide in the blister lock in which decompression took place, (3) vigorous muscular exercise immediately before the decompression, due to the ascending 70-ft ladder, (4) chilling because of the temperature difference between the hot face and the cold decompression chamber It is recommended that lock-keepers be properly trained and given sufficient authority for their task, that a recording barograph be attached to any chamber in which decompression of men takes place, that the blister lock be ventilated or "cleared" during decompression, and that the men wait for 10 minutes after climbing the caisson ladder before entering it so that their carbon dioxide production will have decreased to resting levels This waiting period will also tend to reduce the effect of exercise in predisposing to bends If possible, dry clothes should be put on before entering the decompression lock, and the lock should be kept warm during decompression

PUBLIC HEALTH

The Reported Incidence of Glandular Fever An Analysis of a Report of the Public Health Laboratory Service K W Newell J Clin Path 10 20-22 (Feb) 1957 [London]

In recent years pathologists in public health and hospital laboratories in England and Wales have been voluntarily making weekly reports on infectious diseases diagnosed in their laboratories to the director of the Public Health Laboratory Service Infectious mononucleosis is on the list of diseases for which reports are made In 1955 pathologists were asked to give the age, sex, and occupation of the patient for for each case diagnosed Though about 98% of the hospital and public health laboratories in England and Wales take part in the reporting, it does not necessarily follow that every laboratory invariably reports cases of infectious mononucleosis In a preliminary study in 1954 efforts were made to obtain detailed information on the titers obtained in the Paul-Bunnell test and on whether or not absorption tests were made, but the interpretation of reports from so many different pathologists was difficult, and in the main study in 1955 pathologists were only asked to state whether they based their diagnosis on the results of serologic or hematological tests or both

In 1955 pathologists reported 1,861 cases of which 1,769 were diagnosed serologically, alone or in conjunction with blood or clinical examinations, and in 92 findings were similar to those of infectious mononucleosis clinically and hematologically, but serologic findings were negative The analysis deals only with the 1,769 serologically confirmed cases It was found that 50% of the cases were in children under 15 years of age, but only 39% of those in persons between 15 and 19 were in males Infectious mononucleosis in adults was more frequent during the summer, whereas in children under 15 there was no seasonal peak, the distribution being about the same throughout the year Attack rates seemed to be higher in the south of England than in the north From the records on the occupations of 62% of the patients between 16 and 34 years, it appeared probable that occupational differences could be explained by the accessibility of diagnostic facilities The age groups with the highest incidence appeared to be similar in a number different occupations

BOOK REVIEWS

The Early Detection and Prevention of Disease Edited by John P Hubbard M D George S Pepper Professor of Public Health and Preventive Medicine, University of Pennsylvania School of Medicine Philadelphia Cloth $7 50 Pp 350 with 2 illustrations Blakiston Company (division of McGraw-Hill Book Company Inc) 330 W 42nd St New York 36, 95 Farringdon St London, E C 4 England 253 Spadina Rd Toronto 4, Canada, 1957

Some 28 contributors, working in a variety of fields have attempted to set down as briefly as possible the salient points in disease prevention It is surprising, considering space limitations, how much that is of factual importance they have succeeded in presenting Not all diseases could be considered, but the major ones seen in daily practice are broadly viewed Most diseases enter the body via the respiratory or alimentary systems This is especially true in the case of young children, adolescents and adults up to 45 years of age Older people are more likely to suffer from metabolic disturbances Chapter 15 by Klaus Hummeler, deals with viral diseases of the respiratory tract, especially influenza In 1933, an influenza virus was first isolated and identified as a specific pathogen Seven years later an "A and a "B strain, quite different from each other in many respects, were recognized Since then a 'C and possibly a 'D (Japanese) strain have been studied Vaccines made from various strains are only partially successful The antibiotics effective against some viruses have little or no effect against this disease Owing to great changes in the character of strains, vaccines have to be modified from time to time Under optimal conditions the incidence of influenza may be reduced about 90% (less for influenza B) by vaccination

Cancer of the lung is the subject of chapter 16, by Katherine R Boucot, who avoids any extensive allusion to smoking as a cause, save to say that in the light of present knowledge, cutting down on excess is merely common-sense management for all smokers Men over 45 years of age who have a distressing chronic cough, hemoptysis, unilateral wheeze, and weight loss are suspect, and should be carefully studied Even so it may then be too late In patients with frequent coughs and colds, a roentgenogram of the chest should be made every six months Early detection and prevention of tuberculosis is the theme of a chapter by David A Cooper We are now able to diagnose early infection of the lungs by clinical, laboratory, and x-ray studies Aminosalicylic acid and isoniazid are valuable drugs, and with their use, the incidence of tuberculosis continues to decline, but the disease is still far from being eradicated For about 20 years, surgery of the lung has progressed, but it is applied chiefly in advanced cases Since tuberculosis is directly transmitted from an infected to a well person, normal social contacts will always make eradication of the disease difficult An introductory chapter on the changing scene and a later chapter on the prevention of first-attack rheumatic fever were written by the editor He states that in every case of rheumatic fever we should search for the Streptococcus pyogenes To examine a throat and simply report it as "very red without taking a culture is poor procedure and may jeopardize a patient s future health There is much more of interest and profit to the reader in this excellent symposium The paper and print are excellent

Fortschritte der Serologie Von Dr Hans Schmidt Second edition Artificial leather 150 marks Pp 1114 XXIII, with 87 illustrations Verlag Dr Dietrich Steinkopff, Holzhofallee 35 (16) Darmstadt, Germany, [1950-1955]

The first edition of this important work appeared in 1933, and the present edition represents an effort to assimilate the immense number of contributions that have been made in the field of serology since that time in both Europe and America Issued in 18 installments, the book is now complete and totals 1,117 pages The six major divisions deal with antigens, antibodies, the antigen-antibody complex, the formation of antibodies, indirect and secondary effects of the antigen-antibody reaction, and special serologic reactions The first division may be taken as an example of the comprehensiveness of the work It contains sections on specificity and the haptene concept, proteins in general, the specificity of proteins, chemically altered proteins artificially conjugated antigens, carbohydrate protein combinations serologic experiments with chemically marked antigens, reactions of simple compounds of known composition, the limits of specificity, microbial antigens bacterial toxins and animal poisons heterogenetic antigens and antibodies, viruses, and phages The other five divisions of the book are equally detailed and comprehensive

Especially to be commended is the author s plan of disposing of his topics in units of a few pages, so that each unit is followed at once by its bibliography and so constitutes a compact and coherent entity Abbreviations and other special terms are defined and used freely within the unit but are not carried over into remote parts of the text, it is therefore easy to find a complete and intelligible discussion of each topic, so that the book is unusually convenient for quick reference The bibliography is copious and accurate, and an appendix issued with the last installment brings the work up to date on such subjects as localization of antigens, effects of ionizing radiations on antibody production, the antitoxic immune globulins, transfer of passive immunity from mother to fetus, coproantibodies, experimental organ-antibodies, autoantibodies, antibody production in tissue cultures, and properdin The author and subject indexes have been prepared with care, and the printing is flawless This book will be indispensable in any library used by immunologists, serologists and clinical pathologists

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated

A Text-Book of Gynaecology for Students and Practitioners By James Young, D S O, M D, F R C O G Consulting Gynaecologist, Royal Infirmary, Edinburgh Tenth edition revised in collaboration with J C McClure Browne, F R C O G F R C S E, Professor of Obstetrics and Gynaecology, University of London London Cloth $9 Pp 253, with 302 illustrations The Macmillan Company, 60 Fifth Ave, New York 11, 1956

This edition appears only two years after the previous one There are two new chapters, one on schistosomiasis (bilharziasis) and the other on syphilis, granuloma inguinale, and lymphopathia venereum Several chapters have been rewritten, the text has been revised, and several new illustrations have been added The authors are not enthusiastic about plastic operations on the oviducts, in spite of the recent extensive literature on this subject They point out that only the smallest doses of estrogens should be used to overcome menopausal symptoms They emphasize that uterine bleeding may occur after the use of estrogens, but they maintain this is produced if the dosage has been somewhat too large and is stopped because of nausea They fail to warn their readers to use the estrogens intermittently and not continuously for long periods of time

The section on operative gynecology is most inadequate and perhaps should have been omitted It occupies only 33 pages Eleven illustrations depict instruments but only two portray vaginal hysterectomy One shows subtotal hysterectomy and one the complete hysterectomy for cancer of the cervix There are very few references in this book In spite of these minor criticisms, the book is outstanding Its popularity and usefulness are attested to by the 10 editions since 1921 This edition, like its predecessors, should prove helpful to students and practitioners throughout the world

Sequeira's Diseases of the Skin By John T Ingram, M D F R C P Physician in Charge, Skin Department General Infirmary Leeds and Reginald T Brain, M D, F R C P Physician in Charge Skin Departments at Royal Free Hospital and Hospital for Sick Children, Gt Ormond Street London Sixth edition Cloth $18 Pp 843, with 489 illustrations The Macmillan Company 60 Fifth Ave New York 11 J & A Churchill Ltd 104 Gloucester Pl Portman Sq, London W 1 England, 1957

The authors of this sixth edition of a well-known English textbook are former students of the late Dr Sequeira Ten years have elapsed since the appearance of the previous edition In view of the marked advances in dermatology during this period, extensive changes have been made in the book and many chapters have been completely rewritten Nevertheless, the volume adheres to the same stereotyped pattern of presentation as its predecessor The general range of skin diseases is covered in detail and the descriptive writing is simple and straightforward Therapeutic procedures are described adequately, although many of the newer ideas, drug information, and techniques are merely enumerated or briefly discussed The adherence of the authors to the formalized and didactic presentation of material has a slightly stultifying effect on the reader The illustrations are clear and in general serve to amplify the text, but a number of the older photographs could have been deleted without detracting from the volume The present edition should continue to serve as a reliable and conservative guide to students and practitioners interested in the subject, although the volume is not nearly as comprehensive and illuminating as some of the other recent textbooks in this field

Mental Health Administration By Jack R Ewalt, M D Commissioner, Massachusetts Department of Mental Health Boston Cloth $5 50 Pp 168 Charles C Thomas, Publisher 301 327 E Lawrence Ave, Springfield, Ill, Blackwell Scientific Publications Ltd, 24-25 Broad St, Oxford, England Ryerson Press, 299 Queen St, W, Toronto, 2B, Canada, 1956

The administration of mental health institutions is no longer considered a job that anyone can do with good intentions but little knowledge or experience Today, in fact, there is an accrediting body that certifies psychiatrists for this position The commissioner of the Massachusetts Department of Mental Health has here written a small volume dealing with administration of mental health departments, community mental health programs, mental health centers, and mental hospitals In this book there are numerous practical recommendations concerning the mundane aspects of administration derived from the author's own varied experiences With all the details, and these certainly not complete, there is a noticeable absence of an explicit philosophy and a sense of values True, the details must be learned and applied to myriad problems, but without a value system they are applicable to institutions and not to the human being who is sick and suffering The clothing requisites per 1,000 patients per year or the number of domestics in a special type of school may be significant for the concept of organization but are irrelevant to the treatment goals unless the meaning of all services is oriented to the specific ends Therefore, this is not a good reference book but a manual of operations for those who need to know the means but not the end

Pregnancy and Birth A Book for Expectant Parents By Alan F Guttmacher Director of Gynecology and Obstetrics Mt Sinai Hospital, New York [Some of material in this book appeared in different form in author's book Into This Universe] Cloth $4 50 Pp 335, with drawings by Anthony Ravielli The Viking Press, Inc, 625 Madison Ave, New York 22 Macmillan Co of Canada, Ltd 70 Bond St, Toronto 2, Canada 1956

This book provides an answer to the inquisitive mind of the modern mother It cannot be compared with any previously published manual for expectant parents, as it is truly a textbook of obstetrics written in terms that the average lay person can comprehend It goes into much greater detail than any previous volume written for the expectant parent The author has made a definite effort to be precise and to explain frequently used medical terms in language that can be easily understood by the nonmedical public The book is written in his characteristically clear and interesting style, so that one can easily read this book from cover to cover

Present-day emphasis on knowledge about pregnancy and reproduction has been far in advance of the literature available for the lay public Therefore, this book will provide answers to those expectant parents who desire more than superficial information It will probably serve a more important purpose as a reference for those wishing medical information in terms that are easily understood The index is extremely complete and contains medical headings, as well as terms frequently used by the laity This book can be highly recommended to expectant parents

Occupational Therapy Principles and Practice By William Rush Dunton Jr M D and Sidney Licht M D Second edition. Cloth $8 Pp 373, with 17 illustrations Charles C Thomas, Publisher 301-327 E Lawrence Ave Springfield Ill , Blackwell Scientific Publications Ltd 24-25 Broad St Oxford, England Ryerson Press 299 Queen St W Toronto 2B, Canada, 1957

Extensive revisions have been made in this new edition of a leading book in its field Especially to be noted is the revision of the chapter on upper extremity amputees Emphasis is placed not only on the types and working mechanisms of a variety of prosthetic devices but also on details of retraining the amputee from the physical and psychic standpoints Other major changes involve the sections on occupational therapy for children, bibliotherapy, and psychotherapy The chapters on drama in the first edition have been replaced by those on the role of music and recreational therapy (games) The chapter on occupational therapy in tuberculosis could have been shortened, in view of therapeutic advances and shorter sanatorium care Throughout the book careful attention is given to the need for physician-supervised occupational therapy departments and the need for close teamwork in treating patients requiring rehabilitation

Clinical Use of Radioisotopes By William H Beierwaltes M D Associate Professor of Internal Medicine and Coordinator Clinical Radioisotope Unit University Hospital Ann Arbor Mich , Philip C Johnson M D Assistant Professor of Internal Medicine and Chief Radioisotope Unit Veterans Administration Hospital Oklahoma City and Arthur J Solari, B S , M S Instructor in Radiation Physics Department of Radiology University Hospital, Ann Arbor Cloth $11 50 Pp 456 with 126 illustrations W B Saunders Company, 218 W Washington Sq Philadelphia 5 7 Grape St , Shaftesbury Ave London W C 2 England 1957

This textbook is eminently suited for the beginner in the use of radioisotopes Its major assets are a uniformly high level of clinical judgment and the presentation of technique in recipe style, in such detail that a novice with skill in general laboratory work may expect to use isotopes successfully Included in this recipe style are detailed descriptions of virtually every isotope tracer technique in clinical use The coverage of physics is somewhat less satisfactory, being marred not only by a failure to convey the intended meaning but also by typographical errors, as in the exponentials, which will serve only to confuse the beginner The section on physics in relation to health is, however, well done The chapters on the clinical uses of radioiodine are especially useful

Muscle Relaxants in Anesthesiology By Francis F Foldes M D Director, Department of Anesthesia, Mercy Hospital Pittsburgh Publication number 294, American Lecture Series monograph in Bannerstone Division of American Lectures in Anesthesiology Edited by John Adriani M D Director Department of Anesthesia, Charity Hospital New Orleans Cloth $5 50 Pp 210 with illustrations by Margaret M Croup Charles C Thomas Publishers, 301-327 E Lawrence Ave Springfield Ill Blackwell Scientific Publications 24-25 Broad St Oxford England Ryerson Press 299 Queen St , W Toronto 2B Canada 1957

The muscle relaxants were introduced into clinical practice about 15 years ago This book summarizes the laboratory and clinical experience that has accumulated since that time It is informative, yet not overwhelming in detail The author appears biased in favor of succinylcholine but perhaps this attitude is justified The statement is made that when employed judiciously, cognizant of their pharmacological effects, other than those exerted at the neuromuscular junction, the muscle relaxants will increase rather than decrease the safety of the patient It is doubtful that evidence is yet available to justify this conclusion Occasional errors in spelling are surprising, for example, "afferant and "thiopenthal The format is attractive, and the book can be recommended to those studying as well as those practicing anesthesiology

Out of the Test Tube The Story of Chemistry By Harry N Holmes Ph D LL D Fifth edition Cloth $4 50 Pp 313 with 102 illustrations Emerson Books Inc 251 W 19th St New York 1957

This book is intended to interest the layman in chemistry and to make him more appreciative of the part this science plays in daily life The various chapters make light interesting reading for the author chooses his examples from experiences familiar to everyone The author covers briefly such topics as chemical warfare, hydrogen water inert gases, insects dyes, sugar and fats It is doubtful whether the physician would find much in the book that is new The last edition appeared in 1943 The facts and figures have been brought up to date but otherwise the book is little changed from the previous edition A chapter on atomic power has replaced a chapter on postwar chemistry

Modern Office Gynecology By George Blinick M D F A C S Attending in Obstetrics and Gynecology Beth Israel Hospital New York City and Sherwin A Kaufman M D F A C S Associate Attending in Obstetrics and Gynecology, Beth Isreal Hospital Cloth $4 50 Pp 218 with 47 illustrations Lea & Febiger 600 S Washington Sq Philadelphia 6 1957

A compend is, at best, a fragmentary presentation of knowledge and the authors have shown unusual recognition of the limitations of a pocket edition One-third of this volume is devoted to a well-chosen bibliography, and, in each instance, a sentence or two prepares the reader for what may be expected in the more detailed articles Thirty pages of line drawings clarify the text The general practitioner and the casual worker in this specialty should find this small volume quite worthwhile

QUERIES AND MINOR NOTES

ARTIFICIAL KIDNEY

To THE EDITOR —*For some time several members of the staff of a hospital have been interested in the purchase of an artificial kidney Several models have been investigated, including the "pressure cooker" type, which could be manufactured for a few dollars Please indicate the available kidneys, listed in the order of their functional capacity*

David B Thornburgh, M D , Marietta, Ohio

ANSWER —There are a number of very efficient and satisfactory types of artificial kidney devices available on the market The principal problem that presents itself in equipping a hospital with one of these devices, however, is not the type of kidney obtained so much as it is the need for an effective team of workers who are well versed in its manipulation and who are constantly available to apply it when needed So often a hospital procures one of these complicated pieces of apparatus without appreciating the fact that its use requires a well-trained team of workers who have had considerable experience in its use and who are available when called upon at short notice Unless such a team is available, it is an unwise expenditure of money to procure any such apparatus The simple pressure-cooker type of artificial kidney is by far the cheapest available, but even it cannot be obtained for "a few dollars," as reported in the lay press However, even this apparatus requires a trained team for its use The simplest procedure, which requires no special apparatus and which is entirely adequate for most purposes in which an artificial kidney is desired, is the use of intermittent peritoneal lavage by the simplified procedure as described by Grollman (Acute Renal Failure, Springfield, Ill , Charles C Thomas, Publisher, 1954) It is this consultant's advice, therefore, that the personnel who will be responsible for carrying out the procedure first become acquainted with the various procedures available, including intermittent peritoneal lavage, and then purchase the type of apparatus with which they have become familiar Otherwise the hospital will merely be saddled with the possession of another complicated piece of apparatus, the use of which by inexperienced personnel may entail more harm than benefit

PORPHYRIA

To THE EDITOR —*Is there a successful or even helpful treatment for porphyria?* *M D , Wisconsin*

ANSWER —An effective, reproducible form of treatment for porphyria is not available Convincing evidence concerning the value of any but the most nonspecific forms of therapy is lacking Prophylaxis is stressed in the management of acute intermittent porphyria, this includes avoidance of alcohol, barbiturates, and other toxic agents which have been shown to affect the disease adversely Chloral hydrate, opiates, and paraldehyde may be employed for relief of pain and apprehension Maintenance of nutrition and fluid and electrolyte balance are important objectives in treatment Avoidance of actinic and mechanical trauma is of major importance in managing the cutaneous symptoms Conflicting opinions have been expressed concerning the effectiveness of cortisone and corticotropin (ACTH) in treatment of porphyria, dramatic remissions and complete failures have been reported Congenital porphyria is treated with hematological support and judicious splenectomy

COMPARISON OF PATCH AND INTRADERMAL TUBERCULIN TESTING

To THE EDITOR —*Please discuss the relative merits of the Vollmer patch test and the Mantoux skin test for tuberculosis Is the degree of discrepancy between the two such that the less accurate one could not be safely used for screening an elementary school population? How does one interpret the result when the two outer test areas are red, with distinct borders but not raised, and when, furthermore, these reaction areas disappear about four days after the removal of the patch? In the mass application of patch tests, what errors should be avoided in the application of the patch?*

L David Comstock Jr , M D , Dowagiac, Mich

This inquiry has been referred to two consultants, whose respective replies follow —ED

ANSWER —The Vollmer patch test is alleged to have a 20% discrepancy when compared with the intradermal tuberculin test at proper dosage These discrepancies are both false positives and false negatives Therefore, the patch test cannot be used for any dependable studies and can be thought of as being merely a substitution for a Mantoux test under circumstances where it would be very difficult or inconvenient to use the latter, or where parental consent can be obtained for the patch test but not for the Mantoux test The Vollmer test is safe, of course, but it should not be used in screening an elementary school population

The test result as outlined in the question should be read as negative Hazards in using the test can be avoided by placing the patch where the child cannot remove it (between the shoulder blades, for example) and by issuing instructions as to washing and bathing while the patch is on, as it must be kept as dry as possible

ANSWER —The forerunner of the Vollmer patch test was introduced and considerably used by Lautier, of France, in 1908

The answers here published have been prepared by competent authorities They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply Anonymous communications and queries on postal cards cannot be answered Every letter must contain the writer's name and address but these will be omitted on request

A sizable number of comparative studies have been made with the patch test and the intracutaneous (Mantoux) method of administering tuberculin Some workers have found a discrepancy of approximately 30% in favor of the intracutaneous method Others have reported less difference in the results of the two tests

Although it is generally agreed that the intracutaneous method is more accurate, the patch test is now used rather extensively in survey work, where, for one or more reasons, it does not seem feasible to use the intracutaneous method For example, in St Louis, the Academy of General Practice as a public service has administered the patch test to 125,000 school children with good results The Iowa Tuberculosis and Health Association and the Iowa Trudeau Medical Society are employing the patch test in a statewide certification-of-schools project

Allergy to tuberculoprotein among infected children is usually at a high level, since their infections were acquired relatively recently because of their age Therefore there has not been time for allergy to wane to any great extent

It is usually thought that the patch test yields results comparable to the first dose of original tuberculin or purified protein derivative administered intracutaneously Therefore, those who do not react to the former should then have a second dose of the latter administered However in survey work among school children this usually is not done

Areas of redness of the skin from either method of administration are not considered as tuberculin reactions The usually accepted characteristics consist of an area of edema or induration, or both, of 5 mm or more in diameter

Errors to be avoided in administration of the patch test include failure to cleanse the skin thoroughly with a fat solvent, applying the patch where the child can reach it and remove or loosen it (the interscapular area is a good location), applying the patch loosely so that the tuberculin is not in constant contact with the skin, and removing the patch in less than 48 hours

INDISCRIMINATE PRESCRIBING

To the Editor —*Is there any scientific basis for what seems to be an almost indiscriminate prescribing of the multiple vitamin preparations, particularly those that contain a long list of minerals and even the male and female sex hormones? This does not refer to the therapeutic use of vitamins when indicated*

Connell H Miller, M D Sligo, Pa

Answer —The indiscriminate prescribing of any medicament is to be deplored The relative innocuousness of vitamins does not justify exception of them from this attitude Simple combinations of reasonable quantities of those vitamins for which there is a recognized human requirement have a legitimate place in the treatment of deficiency states, in so called "protective therapy" (as a preventive measure in instances in which some physiological or pathological process increases the requirement above the usual level), or as supplements to nutritionally restricted dietaries The practice of prescribing vitamins without establishing a clear diagnostic reason is to be discouraged The deliberate employment of a vitamin preparation as a placebo is not dishonest, but when so employing vitamins the physician should clearly recognize the reason for the prescription and should consider its cost to the patient

The dosage of vitamins prescribed should bear some relationship to human requirements for therapeutic use, multivitamin preparations containing five times or so the daily recommended allowances (Food and Nutrition Board, National Research Council Publication 302, 1953, p 36) of the factors are reasonable, for supplementary use, amounts equivalent to the daily recommended allowances are adequate In the instance of the fat-soluble vitamins A or D, gross overdosage leads to states of hypervitaminosis

There is no sound justification for most vitamin mineral combinations, especially for those that purport to contain long lists of "trace minerals and other essential elements" If mineral deficiencies exist, they are unlikely to be directly related to vitamin lack Combination of sex hormones, antibiotics, or other therapeutic agents with vitamins is based on conjectural reasoning and a paucity of well-considered evidence The dosage of the nonvitamin component in such combinations is often ineffectively small, but the formulation is inordinately expensive The administration of such combinations should be limited to the exceedingly rare instance in which both agents are clearly needed and the dosage level is effective A decision to use multivitamin preparations, alone or in combination with other medicaments (hormones, minerals), should in each instance be based on a careful analysis of the individual patient's needs and must not serve as a cover for ignorance as to the nature of the patient's illness

PROLONGED POSTPARTUM BREAST SECRETION

To the Editor —*A 21-year-old woman gave birth to her second child 18 months ago Breast feeding was unsuccessful due to the watery nature of the milk, although the breasts were engorged Since that time, the patient has had a more-or-less continual secretion of breast fluid The fluid is thin and yellow-tinged and very irritating to the skin Secretion is worse from the 10th day of the cycle and lasts right through the last day of the period Large doses of testosterone help the condition slightly Premarin has no effect The secretion is bilateral, and both breasts are perfectly normal to palpation*

M D, North Carolina

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —This is one of the most annoying of all postpartum complications The incidence is fairly rare and the duration usually short, although several cases of 10 to 12 years' duration have been recorded Once breast feeding is judged not to be feasible, prompt attention should be given to the breasts By accepted methods and possibly by endocrine therapy, the secretion is as a rule controlled Persistent and prolonged secretion can become a distressing symptom, as in this patient Tincture of benzoin compound should be applied to the skin (a silicone solution has recently been tried for skin protection), the breasts should then be bound tightly and evenly with bland adhesive tape, and methyl testosterone, 10 mg daily for 14 days, should be given Paradoxically, it has been found that injection of the newer progesterone preparations (Delalutin, 250 mg) once a month lessens the secretion from the breasts during therapy In the past, x-ray therapy and even mastectomy have been recommended, which is indicative of the severity of this symptom but certainly these are not considered at present One should rule out the possibility of other pathology such as changes in the anterior pituitary as galactorrhea is a symptom of certain types of endocrinopathy Roentgenogram of the sella turcica should be made Eighteen months certainly is a long time for both patient and doctor but the prognosis, if there are no complications, is favorable

Answer —While the described breast secretion is not completely typical it seems to be a variant of galactorrhea When this condition is seen in association with amenorrhea, adenomas of the pituitary gland have frequently been discovered, and it is suggested that x-ray studies of the sella turcica be made The condition has not infrequently been resistent to treatment Fluid restriction, adequate support of the breasts, and avoidance of manipulation is suggested On the assumption that the secretion may relate to some excess pituitary stimulation, relatively large doses of estrogen have been employed, as, for example, 10 mg of Premarin and diethylstilbestrol, orally, from the end of menstruation for the succeeding two weeks On occasion, the administration of 5 mg of progesterone by injection for 4 doses at three-day intervals, begun at midcycle, has been of benefit

CHRONIC CONJUNCTIVITIS

To the Editor —*A patient with chronic conjunctivitis has not improved with antibiotic, allergic, and immunological treatment A culture disclosed some diphtheroid organisms, similar to those found in some ulcerative cutaneous lesions in service personnel, which responded to local use of antitoxin in the form of wet dressings Is there any record of the empirical use of diphtheria antitoxin, diluted or undiluted, by instillation into the conjunctival sac? Are there any risks in such application, assuming absence of sensitivity from previous use of serum?*

W H Elmer, M D , Rockford, Ill

Answer —The only pertinent reference available is 'Des Conjunctives" by A Gabrielides, 1921, page 117, in which undiluted diphtheria antitoxin was used successfully as an adjunct to parenteral therapy The local use of diphtheria antitoxin in experimental animals, as well as culture sensitivity tests, is relatively simple With the exception of a rare strain which is toxic and transferable in animals, diphtheroids are not toxic in human conjunctiva Should local treatment with diphtheria antitoxin be used, supplementary parenteral injection of diphtheria antitoxin is suggested, unless hypersensitivity exists A more frequent cause of the case described is a subconjunctival micrococcic (staphylococcic) infection combined with vascular hypersensitivity The value of toxoid therapy may be experimentally determined with sensitivity tests

PARALYSIS OF EYE MUSCLES

To the Editor —*Could the application of whole-gland pituitary extract used to assist in hair growth have any adverse effects on a patient? A graduate nurse aged 67 years, began this treatment in June, 1956, and used the product every other day for approximately four months, when she noted paralysis of the right internal rectus eye muscle This cleared 3 days later, but 11 days after the onset of the paralysis in the right eye the same muscle of the left eye became paralyzed, and this condition still persists after two and a half weeks There has been no diplopia, tinnitus, or deafness With the attack on the right eye there was slight horizontal nystagmus (quick component to the left) When the left eye became involved, vertigo was very severe, with falling to the right There is no history of eye trouble prior to the onset of this acute illness, and all examinations to date (spinal fluid, skull x-rays, neurological tests, eyegrounds, and blood pressure [135/80 mm Hg]) are within normal limits for a patient aged 67 The only medicament the patient takes is Premarin, 1 25 mg , and methyltestosterone, 10 mg , daily for the past five years because of osteoporosis Could there be some relation between the use of this hair conditioner and the eye involvement?*

Ella M A Enlows, M D , Fort Lauderdale, Fla

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —There is nothing in whole-gland pituitary extract likely to cause a paralysis of the ocular muscles The possible causes of a paralysis of an ocular muscle in a 67-year-old patient include a host of neurological, vascular, and systemic conditions The most likely causes at this age are arteriosclerosis involving the nucleus of the third nerve, a blood dyscrasia, a brain tumor, diabetes, myasthenia gravis or an encephalomyelitis

Answer —No relation could possibly exist between the use of the hair conditioner and the eye involvement The pituitary extract is a protein, and hence it is not absorbed by the skin and is rapidly destroyed by the bacteria of the scalp Any benefit of this topical medicament would be due to the production of local hyperemia and the correction of dryness

As for the eye muscle involvement, the absence of diplopia and ptosis suggests a conjugate deviation due to a supranuclear lesion If so, the movement of convergence should still be elicited With assumption of this mechanism, a single lesion on the left side could explain all the findings In the transient irritative stage the eyes would deviate to the right, simulating a paresis of the right medial rectus, while in the permanent destructive stage the eyes would turn toward the left (i e, to the lesion) and so simulate a paresis of the left medial rectus The causes of supranuclear palsies are varied The postmenopausal osteoporosis in this case suggests a vascular basis, as deposition of calcium in the arterioles is a common factor in all types of osteoporosis The patient's age, 67, and the vertigo immediately associated with the second eye finding suggest a "minor stroke"

TELEVISION RADIATION AND DERMATITIS

To THE EDITOR —*A 40-year-old patient has what appears to be a mild bilateral cicatricial entropion, conjunctivitis, and a generalized facial dermatitis characterized by dryness and dilated peripheral blood vessels For the last seven years he has been employed as a television monitor During this time he has worked seven to eight hours a day, five or six days each week, with his face 12 in (or slightly less) from a television tube, making fine adjustments in the sharpness of the picture on the tube What is the amount and nature of radiation emanating from a television tube source? Could this be the source of ophthalmological involvement?*

Grant B Dallabough, M D , Teaneck, N J

ANSWER —In 1946, when the early impetus of television first struck the New York area, this consultant and others attempted to measure the x-radiation and the ultraviolet radiation from a television tube The glass in the tube absorbed all the ultraviolet rays, and no x-rays coming from any part of the tube were detected It is doubted whether this would be the source of the dermatitis, with entropion and conjunctivitis

TELEVISION RADIATION

To THE EDITOR —*Please supply information as to whether television sets emit radioactive rays and whether there might be some danger especially for children, if they sit too close to the television set*

Artur Philipsborn M D , Cleveland

This inquiry has been referred to three consultants, whose respective replies follow —ED

ANSWER —X-rays produced in the commonly used television sets have energies of 15 000 to 20,000 volts They have little penetration and are absorbed in the faceplate of the picture tube In addition, many sets have plastic or glass plates in front of the faceplate for further safety For tubes using higher voltages 25,000 volts or more, such as the color television tubes, some rays penetrate through the faceplate, and the tube manufacturers warn that safety glass, ¼ to ⅜ in thick, should be placed in front of the faceplate It seems certain that the manufacturers of television sets, in their own interest, will heed the warning of the tube manufacturers in addition to carrying out their own controls so as to ensure the safety of their product

ANSWER —In the course of many years of both clinical and private practice, this consultant has never seen any patient demonstrating any appreciable biological effect from rays emitted by a television tube The rays emitted by the usual tube are similar to the very soft grenz rays The risk of exposure beyond the screen of the apparatus is of little consequence With the new type of television apparatus, however, where the rays are generated at an energy of 25 kv, a type of soft x-ray is produced which may have some biological effect on those viewers who may be in direct contact with the television screen A physicist is better equipped to measure the exact value of the rays emitted by the television tube

ANSWER —It is true that some "radioactive rays" do emanate from the electron tube of a television set However, these rays are extremely soft and are completely dissipated by the glass screen or wooden cabinet of the set Research at the Sarnoff Laboratories, in Princeton, N J , indicates that there are no harmful effects because of radiation from watching or sitting near a television set This is true of children as well as of adults

CONDUCTIVE SHOES FOR USE IN OPERATING ROOM

To THE EDITOR —*Please supply information concerning use of shoes, or metallic clips which can be attached to shoes, so that surgical personnel will be made nonconductive for static electricity The hospital has adequate grounding of equipment, outlets, and electrically conductive flooring in the operating room The only problem is to find a simple piece of apparatus which can be used to see that all personnel in surgery are properly grounded*

Meyer Schindler, M D , San Francisco

ANSWER —First, this consultant would like to correct a common error made when talking about safety measures in hospitals The inquirer in this instance requested information on appliances for shoes that would make surgical personnel "nonconductive for static electricity" It is certain that the information requested is for a simple economical device that will provide contact from personnel to a conductive floor in order to make the individual and floor continuously conductive for static electricity"

A conductor is a material that will permit the flow of electricity over or through it A nonconductor is a material that will not permit the flow of electricity over or through it

Conductive footwear of some type must be worn by all personnel in the anesthetizing locations Conductive soled shoes are available today in many department and shoe stores throughout the United States Since the price is not prohibitive, this consultant feels that doctors, nurses, orderlies, and maids who work in the anesthetizing locations in hospitals should wear conductive shoes Substitutes, such as conductive booties, slip-ons, and snap-on heels, are fairly satisfactory, however, they may prove to be expensive because of frequent replacement and present a nonprofessional appearance The names and manufacturers of various types of conductive footwear may be obtained by writing to the Committee on Hospital Hazards of the American Society of Anesthesiologists

A simple inexpensive device for conductive footwear was described by Virtue and associates in *Anesthesiology* (15 113, 1954) They recommended that an aluminum strip from an intravenous infusion bottle be bent so that it will touch the sock inside of the shoe and then make contact with the floor at the broad part of the heel, it can be held in position with small nails or adhesive. The aluminum strips are satisfactory, unless the wearer has especially thick socks, in which case he should dampen them slightly at the heel.

YELLOW-TINTED GLASSES

To the Editor.—*My hobby is target shooting. I frequently see advertisements for yellow-tinted glasses, designed to increase the contrast and details of the target. These are also supposed to be particularly effective on cloudy or overcast days. I would like an opinion from an ophthalmologist both as to their effectiveness and as to the amount of tint required to attain this.*

John D. Jennings, M.D., Hugo, Okla.

Answer.—Yellow-tinted glasses transmit yellow unchanged, but the short-wave rays of blue and green are diminished. When used at dusk or on overcast days, the yellow becomes relatively brighter than the blue or green. Hence, yellowish animals appear more distinct, and for this reason such glasses have been used by hunters for years. If used to overcome dazzling, a deep tint is required, but on cloudy days a light tint is more advantageous.

SWEAT APPARATUS IN ANIMALS AND MAN

To the Editor.—*Please provide information on which animals are most closely related to humans regarding the sweat apparatus.*

Marvin N. Winer, M.D., Buffalo, N. Y.

This inquiry has been referred to two consultants, whose respective replies follow.—Ed.

Answer.—The structure and function of sweat glands in the pads of the foot and digits of domestic cats correspond closely to those of the eccrine glands of man. The chimpanzee has numerous eccrine glands over its body, but the sweating responses of these glands have not been investigated. The sweat of the horse, the dog, and the ox is secreted by apocrine glands, which are structurally and physiologically different from the eccrine glands.

Answer.—Sweat or perspiration is not found to occur over the general surface of the body in any hairy animal other than the horse. In the horse, certain parts of the skin sweat more readily than others. The base of the ears is the first place for sweat to appear. This is followed by the appearance of sweat along the neck, the sides of the chest, along the surface of the back, and, lastly, the hind quarters. There is no sweating of the legs—the fluid found there has run down from the other body surface. The mule and the donkey sweat with difficulty and then only at the base of the ears. Cattle sweat freely from the muzzle. Sometimes the general surface of the body may appear to be sweating. Sheep do not sweat in the ordinary way, in which the sensible sweat is observed. The pig sweats only on his snout. The dog and the cat sweat freely from the foot pads and the muzzle. There is no sensible perspiration, however, from the general surface of the body.

The sweating process is a continuous one in animals; when excreted in small amounts, the fluid is evaporated as fast as it forms and is passed off as an insensible vapour—hence the name "insensible sweat or perspiration." When the body condition is such as to produce more fluid and the atmospheric condition is unfavorable to its evaporation, this fluid collects on the skin and is ordinarily called sweat or "sensible perspiration."

ABDOMINAL PAIN FOR FIFTEEN YEARS

To the Editor.—*A 40-year-old woman has had right lower quadrant pain periodically for 15 to 20 years. There has been no relation to menses. Treatment has consisted of foreign-protein injections, with some considerable relief. Pain has become so severe recently, with signs of femoral nerve irritation, that operation was undertaken. Operation revealed a small mass in the broad ligament and along the pelvic wall that grossly resembled a sarcoma. Although complete removal of the mass was impossible, considerable improvement followed and lasted for about two months. The pathological diagnosis was chronic granulomatous inflammation of the pelvis, etiology undetermined. No acid-fast organisms were found on stain. No culture was done because of the feeling that the condition was sarcoma. The patient has a positive patch test for tuberculosis and has a sister with draining chest sinuses due to tuberculosis. Her chest x-ray has been normal over the past three years since her last contact with her sister. Currently she is in remission from pain after receiving 40 units of corticotropin (ACTH) on two successive days. Is treatment as such advisable in view of the long history of pain, or should the antituberculosis drugs be tried? The patient is very reluctant to submit to operation again.*

M.D., Ohio.

This inquiry has been referred to two consultants whose respective replies follow.—Ed.

Answer.—Further diagnostic studies should be carried out on this patient in the form of aspiration biopsy of the mass in the broad ligament and along the pelvic wall. This should be done through the vagina with a long, large-bore needle in which a special suction syringe, devised at Memorial Center in New York City and supplied by United Surgical Supply Company, Port Chester, N. Y., is used. Satisfactory material should be obtained for cytological study as well as culture, and further definitive treatment should depend on reports of studies of material taken.

Answer.—The only implication of neurological involvement is the statement "femoral nerve irritation." If this is a true nerve involvement, then the immediate program for the patient should consist of x-rays of the lumbar sacral spine, lumbar puncture, with careful manometric studies, examination of the spinal fluid for total protein, sugar, and cells, Wassermann reaction, and colloidal gold test. The spinal fluid should be cultured and centrifuged for direct smear of precipitate and Papanicolaou stain If there is no evidence of involvement of the spinal vertebrae, pelvis, spinal cord, and cauda equina, then it is the opinion of this consultant that a reexploration is mandatory

PERSISTENT LIVER TENDERNESS AFTER HEPATITIS

To THE EDITOR —*A patient has persistent liver tenderness four and a half months after viral hepatitis He apparently contracted this hepatitis on a tour of the Caribbean After being sick for six weeks, he gradually returned to full-time work Liver-function tests now are practically normal Any suggestion of therapy will be greatly appreciated*

M D, California

This inquiry has been referred to two consultants, whose respective replies follow —ED

ANSWER —It is not unusual to have some degree of discomfort and tenderness in the right upper quadrant following exertion as long as four to six months after the onset of hepatitis One cannot be quite sure what is meant by the statement, "Liver-function tests are practically normal" If this is true for such significant tests as Bromsulphalein dye retention, thymol turbidity, and serum bilirubin, one would think that there would be little reason to be concerned over eventual prognosis at this time There is no specific therapy to recommend Undue fatigue should be avoided, and, when discomfort does occur, greater than usual periods of rest should be taken Hepatic function and physical examination should be checked at intervals of three weeks

ANSWER —The persistence of liver pain and tenderness after apparent recovery from viral hepatitis suggests that the recovery is not yet complete It is stated that the liver-function tests are "practically" normal What tests remain abnormal, and what is their degree of abnormality? A high degree of Bromsulphalein retention is indicative of chronic liver disease A mild hyperbilirubinemia may indicate the presence of a smoldering hepatitis In some cases the presence of one of the sequelae of hepatitis cannot be definitely ascertained without liver biopsy

The treatment of the sequelae of hepatitis is similar to that of the acute disease and consists of rest, high-protein diet, and vitamin supplements The degree of activity allowed should be just short of provoking liver pain and tenderness If hyperbilirubinemia persists, the steroids or corticotropin are useful therapeutic adjuvants

CULDOSCOPY TO DIAGNOSE ECTOPIC PREGNANCY

To THE EDITOR —*What is the value of culdoscopy in the diagnosis of ectopic pregnancy? Is it applicable?*

Thomas C Case, M D, New York

ANSWER —Several series of patients in whom culdoscopic examination has been employed give evidence that this procedure has resulted in the early diagnosis of unruptured tubal pregnancy in a significant percentage of cases The use of proper anesthetic techniques, either local infiltration or low spinal, together with careful introduction of the culdoscope, seems to carry minimal risk In cases of suspected ectopic pregnancy, many prefer preliminary needle puncture of the cul-de-sac to detect the presence of blood in the peritoneal cavity Culdotomy, opening of the cul-de sac to allow palpation and visualization, is preferred by some

BIOPSY OF CERVIX

To THE EDITOR —*Please describe an adequate and acceptable procedure for the biopsy of a cervix showing a velvety erosion surrounding the external os*

M D, New York

ANSWER —Any cervical erosion should be subjected to a routine office biopsy This is a simple procedure and without hazard to the patient A simple punch biopsy forcep is utilized, and tissue is obtained from the 12, 3, 6, and 9 o'clock locations around the external os This four-quadrant procedure eliminates the possibility of missing a circumscribed lesion A cervix from which a biopsy specimen is so obtained is not cauterized or otherwise treated until the pathologist's report is obtained This information will then determine the procedure to be followed

MULTIPLE SCLEROSIS

To THE EDITOR —*A woman patient is suffering from multiple sclerosis Please provide information concerning long-term treatment*

George Welker Jr, M D, Morganfield, Ky

ANSWER —There is no specific treatment for multiple sclerosis, but there is reason to believe that comprehensive medical management helps these patients, and they are certainly entitled to the benefits of good supportive therapy The rationale is outlined by Wainerdi (*M Ann District of Columbia* 23 7, 1954)

CAUTIONS IN USING ARTIFICIAL KIDNEY

To THE EDITOR —*Have any deaths resulted from the use of the artificial kidney for dialysis of poisons? Is it ever the cause of any morbidity? There is considerable interest in its usefulness in poisoning, and a knowledge of any dangers inherent or encountered is essential* *J Greenblatt, M D, Stamford, Conn*

ANSWER —Since patients subjected to dialysis by the artificial kidney for any purpose are in critical condition, it is obviously impossible to state if deaths have resulted from the use of this procedure However, on the basis of experimental studies on dogs, it has been demonstrated that many precautions must be taken if one is to avoid harmful effects Thus the use of an excessive dose of anticoagulant, toxic agents present in the membrane, overloading with fluid, or loss of blood volume into the membrane could prove fatal With proper use by experienced personnel, however, there should be no cause for morbidity or harm from these sources Details of the advantages and disadvantages of the artificial kidney as compared to other procedures are given in "Acute Renal Failure" by Grollman (Springfield, Ill, Charles C Thomas, Publisher, 1954)

Details on Patients in Proprietary Nursing Homes • •

DOCTOR PROCUREMENT BILL UP FOR SENATE ACTION

A new doctor-procurement bill has passed the House and is awaiting Senate action There is every prospect that it will become law before the expiration July 1 of the "doctor draft which has been on the statute books since the Korean war in 1950 The new proposal, in the form of an amendment to the regular draft act, provides for the selective call-up for the next two years of physicians, dentists, and allied specialists through age 35

The group subject to call are those whose obligation under the regular draft has been delayed through educational deferments In other words, physicians would be called up as members of their profession rather than by age groups Service would be the same as that for the regular draft—two years

Rep Paul Kilday (D, Texas), floor manager for the bill, pointed out to the House that the discrimination remaining in the new proposal (requiring a man to enter service because of his profession) is intended to be counterbalanced by the amount of compensation he receives and the rank at which he is commissioned when he enters service

Rep William Bray (R, Ind) noted that, when the "doctor draft' was passed in 1950, physicians up to the age of 50 could be drafted, which caused "a great deal of hardship in many communities where doctors had been practicing for many years' But he said that each time the matter came before the committee the age has been lowered, so that now it is down to age 35

The House also indorsed the Armed Services Committee recommendation that the national, state, and local medical advisory committees be continued The Defense Department original draft extension proposal left out these committees The American Medical Association strongly urged their continuation

WHO ACCEPTS U S INVITATION FOR NEXT YEAR'S MEETING

As expected, the World Health Assembly will hold a 10th anniversary commemorative session and the 11th session of the assembly in the United States in the spring of 1958 The American invitation, approved by Congress last year, was accepted unanimously by the assembly s committee on administration, finance, and legal matters at the Geneva meeting Favorable action by the assembly itself was assured

Congress has authorized expenditure of $400,000 to compensate the assembly for the additional costs of holding the meeting in the United States, away from WHO s permanent headquarters in Geneva The assembly is the governing body of World Health Organization

The invitation to the assembly was presented by Rep John Fogarty (D, R I), a member of the U S assembly delegation The acceptance was received by Dr Leroy E Burney, surgeon general of U S Public Health Service, who heads the U S delegation to WHO Dr Fogarty assured WHO that this country would do "all in its power' to make both sessions successful A city has not yet been selected for the meetings

In other actions the assembly

1 Called for greatly increased contributions from "all sources to insure success of the world-wide malaria eradication campaign, which it is estimated will cost 15 million dollars yearly for five years

2 Adopted a resolution recommending that the five-year term of Dr M G Candau, WHO director-general be extended for another five years after its expiration date of July 21, 1958 The resolution states The services performed by Dr Candau have contributed immeasurably to the successful operation of WHO and it is desirable that he continue as director-general for a period beyond the expiration date of the present contract' Dr Candau is a native of Brazil

3 Adopted a 1958 budget of $13,500,000, an increase of $2,800,000 over this year s budget The U S share will be one-third The figure is half a million dollars less than requested by Dr Candau, but $1,500,000 more than proposed by the U S

HEARINGS ON DANGERS OF RADIATION EXPOSURE

The head of the Atomic Energy Commission s division of biology and medicine has informed a congressional hearing that to say that we will tolerate no increase in exposure to radiation is equivalent to saying that we will make no use of nuclear energy

This dilemma, Dr Charles Dunham pointed out to the joint atomic energy subcommittee on radiation applies equally well to the use of radiation in medical practice

A physician uses X-rays to diagnose an injury or a disease because he believes that the benefits to the patient outweigh any detrimental effect of the X-rays " Dr Dunham testified He was lead-off witness in a three-week inquiry into problems of radiation stemming from bomb tests

"Although the X-ray doses required for diagnosis are generally small, a physician could not justify exposure of the patient without some reason A physician may use larger doses on a patient suffering from cancer The treatment is obviously justified when one weighs the anticipated benefits against the possible undesirable effects'

Dr Dunham argued that the development of nuclear energy and the production of radioactive materials are inseparable "With moderate effort, we can prevent release of a large fraction of these materials With greater effort we can further reduce the release However, if we continue to reduce the fraction we are willing to release, we eventually reach a cost of control which makes the operation prohibitive At some poin — we must balance the undesirability of further incr

---

From the Washington Office of the American Medical Association

in the quantity of radiation to which we are subject against the benefits to be anticipated from whatever application of nuclear energy we are considering'

Chairman Chet Holifield, who conducted extensive hearings last year as head of a committee on civil defense problems, said it was not the purpose of the joint committee to draw any moral, political, or philosophical conclusions, nor to get into the question of disarmament Rather, the subcommittee is devoting its attention mainly to the radioactive fall-out problem and to a possible projection of what the hazards are

Mark Mills, Ph D , of the University of California Radiation Laboratory, said scientists working to tame fusion (the reaction that powers the H-bomb) are not yet at the stage of the 1942 Chicago fission reaction which led to atomic energy

HEARINGS ON UNION WELFARE FUNDS

Hearings are underway before a special Senate subcommittee of the Labor and Welfare Committee on several bills providing for various degrees of federal supervision over union welfare funds, including their health and disability insurance aspects Chairman John Kennedy (D , Mass) and other members of the committee said they were anxious to get Senate action on some plan before adjournment

Opening the hearings, Senator Kennedy said grave responsibility rests on the federal government to safeguard these plans for their beneficiaries the estimated 75 million workers and their families who look to them for some form of protection

Earlier studies, including the Dave Beck investigation, have disclosed unsound practices among some of the funds, where workers rights are being jeopardized or ignored,' Senator Kennedy declared However, like others on the subcommittee, he explained that the vast majority of the funds are run efficiently and honestly

Early discussion at the hearings indicated that the subcommittee is not in agreement on how far the federal government should go in checking up on the funds Senator Gordon Allott (R , Colo), whose bill is one of those under consideration, warned against all-over national legislation or federal action in areas where states 'are awakening to their own responsibilities, as in life insurance

This is the third time in recent years a Senate committee has undertaken to draft legislation for some measure of control over union welfare funds During the 83rd (Republican) Congress, Senator Irving M Ives (R , N Y) was chairman of a subcommittee that studied the subject, and Senator Paul Douglas (D , Ill) headed the group in the last Congress Senator Ives remains on the subcommittee, but Senator Douglas has left the parent committee so is not on the subcommittee

Senator Ives, who is a co-sponsor of the Allott as well as the Douglas bill, summed up his views this way

The need for legislation was readily apparent from the examples of wrongdoing uncovered by these investigations Recent disclosures before the Senate Select Committee Investigating Improper Activities in the Labor or Management Field have served to emphasize the need for prompt action in this and related fields At least $26 billion is now tied up in pension and welfare funds, and annual contributions to such funds are estimated to total an additional $5 billion a year"

Most subcommittee attention seems to center on the Douglas bill and an amended administration bill, measures that are similar in their major provisions Both would require registration of plans, the filing of annual reports, and criminal penalties for misuse of funds or fraudulent reports, and would apply equally to union-managed funds, management-operated funds, and funds run jointly by unions and management

The Douglas bill would put the Securities Exchange Commission in charge of registration, filing of annual reports, and making information in reports available to the press and the general public, whereas the administration bill would give this responsibility to the Labor Department As it is presently written, the administration bill would not exempt any such fund, but the Douglas bill would completely exempt a fund involving fewer than 25 workers, and under most conditions require reports only from funds involving 100 or more workers

Speaking of his bill (which resembles the administration bill in this respect), Senator Douglas said

'This is not a regulatory bill That power of regulation is left to the states It is only a disclosure bill, with obvious added protections against perjury and embezzlement Disclosure, we believe, will serve not only as a deterrent to abuses, but also as an aid to self-policing by those among the unions, employers, banks and insurance companies who recognize voluntary restraints as a desirable alternative to more stringent federal regulation"

STATISTICS ON PATIENTS IN PROPRIETARY NURSING HOMES

The Public Health Service is publishing the first detailed study of patients in nursing homes, including information on age, sex, and disabilities Data were gathered through the joint efforts of the Commission on Chronic Illness, the health departments and agencies of 13 states, and the PHS

Here are some findings

1 The average age of patients in proprietary nursing homes is 80, and all but 1% are over 45

2 Two-thirds are women

3 One-fifth are confined to bed all the time, and less than half can walk without assistance

4 More than half the patients are mentally confused, at least part of the time

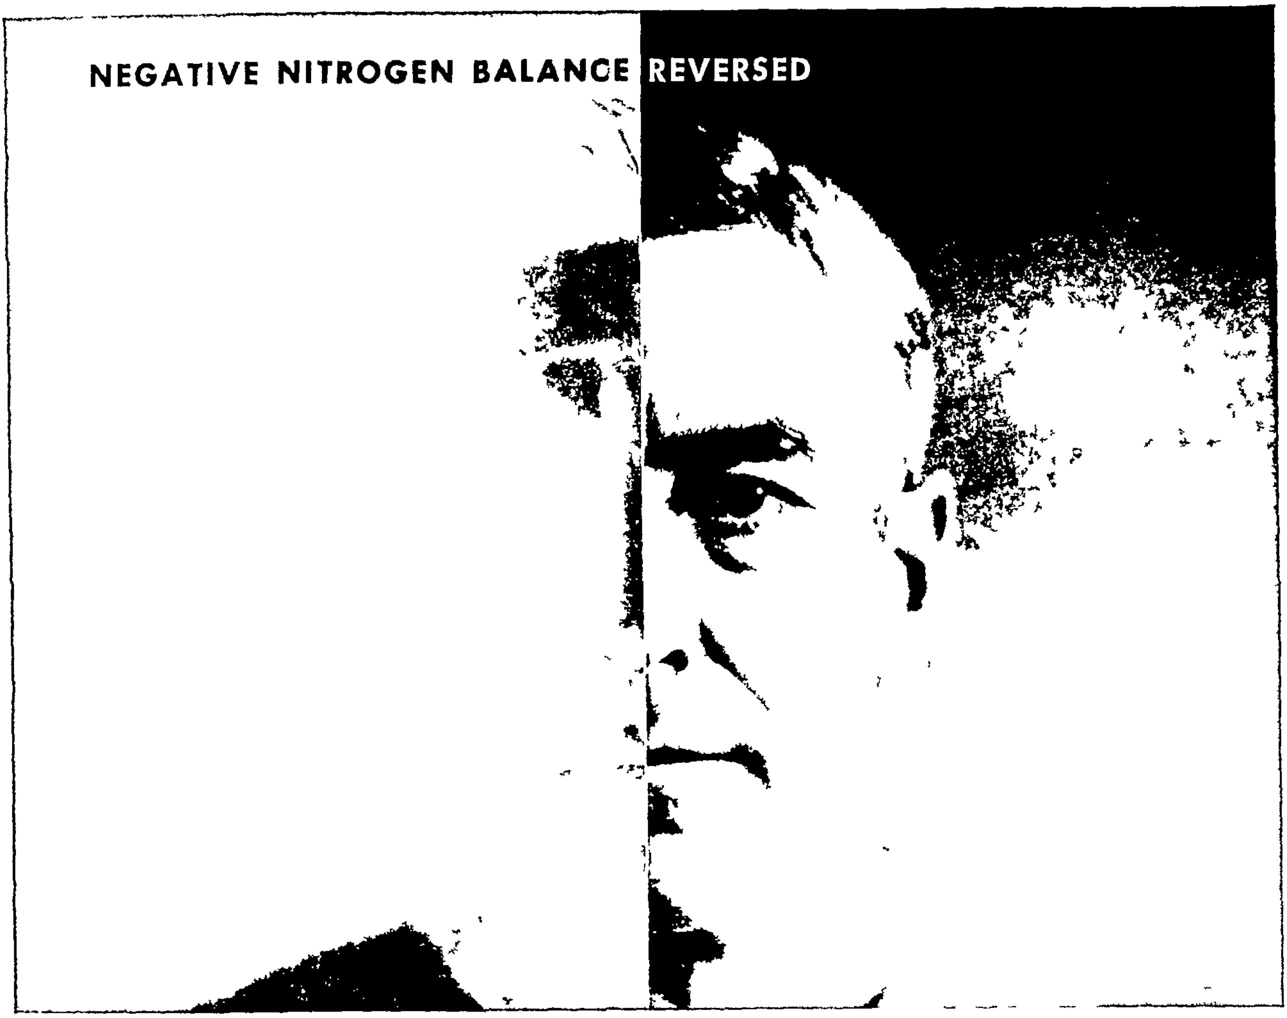
5 Two of every five have cardiovascular conditions and many have arthritis or rheumatism

Information also is given on type of care received, charges and how money is raised for payment, type of staff in the homes, occupancy, and age of buildings While no actual count was made of proprietary nursing homes patients, the total is estimated at 135,000

MISCELLANY

Drs Lyndon E Lee Jr and Alfred M Steinman have joined the VA's Department of Medicine and Surgery research and education service Appointed to newly created positions, the men will be, respectively, chief of surgical research in extra-VA division and assistant chief of the clinical studies section Another VA employee, Miss Irene Grant, social work specialist in the Washington central office, has received a meritorious service award for developing the foster home program for mental patients and other disabled veterans

The Air Force recently held medical meetings in Europe and in the Far East Dr Alton Ochsner was guest speaker at the Far Eastern Air Force medical meeting, while Dr Frank W Hartman, medical research advisor to the Air Force surgeon general, attended the aeromedical symposium in Germany



Nilevar® stimulates protein synthesis, corrects negative nitrogen balance

Increased nitrogen loss, with resulting negative nitrogen balance, occurs in infection, trauma, major surgery, extensive burns, certain endocrine disorders and starvation and emaciation syndromes The intrinsic control of protein metabolism is lost and a protein "catabolic state" occurs A patient requiring more than ten days of bedrest usually has had sufficient metabolic insult[1] to precipitate such a "catabolic" phase

Nilevar (brand of norethandrolone) has been used in patients with varied conditions including hyperthyroidism, poliomyelitis, aplastic anemia, glomerulonephritis, anorexia nervosa and postoperative protein depletion The patients gained weight and felt better It was concluded[2] that "the drug certainly caused a reversal of rather recalcitrant or progressive catabolic patterns of disease "

Nilevar is unique among anabolic steroids in that androgenic side action is minimal or absent

The suggested adult dosage is three to five tablets (30 to 50 mg) daily For children 1 5 mg per kilogram of weight is recommended

The Celebrated Frere Jacques—Cutting for the Stone

Frere Jacques said that his name was Jacques Beaulieu, he came from the village of Langfonnierre in Burgundy his parents were very poor, and his only education was to learn to read and write imperfectly He joined the army, and at the age of twenty-one years he became the servant of a quack named Pauloni who cut for the stone Frere Jacques claimed Divine inspiration as the origin of his operation, but even in Paris he performed other operations which were peculiar to quacks, so it seems certain that he learned the operation from Pauloni He spent six years with Pauloni, and when the latter went to Venice Frere Jacques stayed at home and commenced operating on his own account As he approached the age of forty years [about 1697] he became deeply religious, although he never seems to have taken any religious vows, he assumed the habit of a monk lived the life of a hermit existing on bread and soup and resolved to devote his life to charity He operated successfully on a canon of the church, who persuaded him to go to Paris, giving him a strong recommendation to the officials of Notre-Dame He must have had a strong personality, as in spite of this extraordinary mode of dress he became the idol of the vulgar and the bane of the profession

When he arrived in Paris he introduced himself to the Charite hospital through the first surgeon Marechal, but the physicians would not allow him to operate The friendly canon had introduced Jacques to De Harley, first president of the Parliament of Paris who became his friend and protector De Harley ordered Dr Mery surgeon of the Hotel-Dieu, to attend an experimental operation by Frere Jacques on a dead body a stone having been placed in the bladder above the pubis The operation of Frere Jacques at this stage was very much of a hit-or-miss affair, if he hit the stone at the first plunge all was well if he missed it he felt around for it with a sharp knife, and you can well imagine the damage that was done It must have been the latter which caused Cheselden to make the following statement in his book

> They say he performed the operation without any direction and without any knowledge of the parts he was to cut a thing not to be mentioned without horror But of late his character has been set in a very different light and though it is more than probable he himself knew not what he did, yet there are now, those who pretend to tell us exactly though if their testimonies are to be regarded there is no place that he did not cut one time or other

Frere Jacques became dispirited and left Paris and went to Fontainebleu where the Court was situated at that time He had letters of introduction to the Court physicians and was well received, and here he met Fagon a physician of note He first operated successfully on a boy in the presence of Fagon Duchesne and Felix, all Court physicians or surgeons, who were very impressed He then performed six more operations four in hospital and two on private patients all were successful and the whole Court was deeply impressed in his favour When the Court returned to Versailles, Frere Jacques returned to Paris strong in reputation and friends His progress was rapid and enterprising but the surgeons still opposed him

Frere Jacques for a time became an itinerant lithotomist, visiting Germany and Holland and operating with some success His operation had made a deep impression on Fagon and in 1700 Fagon recalled him to Paris and took him into his house For many months they studied anatomy, Frere Jacques was introduced to the grooved staff, and it is stated that, after th first incision, never again did Frere Jacques's knife leave th groove of the staff Fagon put the operation on a scientifi basis

Fagon himself had a stone, and at this time two men, Fago himself and the Marechal de Lorges, decided to be operated on by Frere Jacques Fagon at the last moment changed his mind, he was operated on by Marechal, a surgeon who had learnt Frere Jacques's operation, and he recovered Th Marechal de Lorges, a wealthy nobleman, was more faithful but cautious He assembled at his hotel 22 poor people afflicted with stone Frere Jacques operated on the 22 with complete success Then the Marechal de Lorges was operated on and on the second day he died in torture The death of one so well known was too much, and Frere Jacques left Paris never to return —P Hopkins, Cutting for the Stone, *The Medical Journa of Australia,* Jan 26 1957

Relatives' Reactions to Postoperative Condition of Patient

A doctor visited his daughter after a serious abdominal operation and told his wife, She's doing very well His wife saw the child later in the day and came home very upset and said to her husband, How could you say she was doing well She looked dreadful to me It is a great mistake for relative to visit patients too soon after an operation as they will almos always be shocked by what they see, even though the patien is reported to be as well as can be expected by the doctor In one hospital passes were issued to relatives on the morning of the patient's operation and they sometimes arrived in the ward when the patient was being brought back from the theatre reeking of anaesthetic, possibly vomiting and uttering those cries and groans which often accompany that not unpleasant period of semiconsciousness which follows an operation and which may be most distressing to anxious relatives An exception to this post-operative ban on relatives is when the patient is a child, for nothing can comfort and calm a child more than the presence of his mother as consciousness is gradually regained It is, however essential to explain to the mother exactly what to expect, a child coming round from a tonsillectomy smeared with bloody vomit is not a pleasant sight, but even the most sensitive parent will accept this if she is forewarned Quite apart from operations patients who have been seriously ill may be so changed in appearance that relatives seeing them for the first time may be very distressed unless they are prepared, this reaction on the part of the visitor may itself distress the patient and cause him to become alarmed about his own condition Children, even more than adults, may be upset by a visit to hospital It is a great shock to a child to see an adult ill or even to see a familiar face without its false teeth, and they should not be subjected to such an experience except for very special reasons —F F Hellier, M D, Patients Relatives as Hospital Visitors, *University of Leeds Medical Journal,* February, 1957

a new dosage form

Compazine* Ampuls

for immediate control of nausea and vomiting when oral administration is not feasible

In 98% of cases treated with 'Compazine' Ampuls during clinical trials, a single intramuscular dose completely stopped nausea and vomiting or reduced its severity enough to permit tablet administration

Dosage An initial dose of 5 to 10 mg (1 to 2 cc) should be injected *deeply* into the upper outer quadrant of the buttock This may be repeated if necessary at intervals of 3 to 4 hours

For further information, see S K F literature

Available 2 cc (10 mg) ampuls in boxes of 6 and 100 5 mg tablets in bottles of 50 and 500

'Compazine'

in arthritis, BUFFERIN® because...

in many of your arthritic cases BUFFERIN alone can safely and effectively provide adequate therapeutic control without resorting to the more dangerous cortisone-like drugs

BUFFERIN is better tolerated by the stomach than aspirin, especially among arthritics where a high dosage, long term salicylate regimen is indicated

BUFFERIN provides more rapid absorption of salicylate than enteric-coated aspirin

even in those cases where steroids are necessary, use of BUFFERIN will allow proper flexibility for individual dosages

BUFFERIN is economical for the arthritic who requires a long period of medication

BUFFERIN *contains no sodium,* thus massive doses can be safely given without fear of sodium accumulation or edema

Each sodium-free BUFFERIN tablet contains acetylsalicylic acid 5 grains, and the antacids magnesium carbonate and aluminum glycinate

Bristol-Myers Company, 19 West 50 Street, New York 20, N. Y.

NEW CONCEPT

not repeat action—
not delayed action—but
continuous antiallergic action

THE UNIQUE OUTER SHELL of the Lontab actually contains 33 mg Pyribenzamine There is no enteric coating to prevent immediate release Thus, the Pyribenzamine Lontab acts faster

THE UNIQUE INNER CORE of the Lontab contains 67 mg Pyribenzamine This core is specially formulated to release the medication at a uniformly regular rate, hour after hour Thus, the antiallergic effect is sustained for as long as 12 hours

Pyribenzamine®
Lontab™

protects your allergic patient
all day or all night

SIMPLY BY TAKING ONE LONTAB in the morning and one in the evening your patient is protected from allergic symptoms 24 hours a day

Prescribe fast-acting Pyribenzamine regular tablets for patients whose symptoms occur periodically rather than continuously

Supply Pyribenzamine Lontabs, 100 mg (light blue)

PYRIBENZAMINE® hydrochloride (tripelennamine hydrochloride CIBA)
LONTABS™ (long acting tablets CIBA)

C I B A SUMMIT N J [illegible]

in seasonal allergies

...as in colds

you can check excessive irritant secretions

and "unlock" the closed-up nose

orally with

NOVAHISTINE®

In the management of seasonal allergies and the common cold, Novahistine works better than antihistamines alone The distinct additive action of a vasoconstrictor with an antihistaminic drug *combats allergic reactions* more efficiently provides marked nasal decongestion and inhibits excessive irritant secretions Novahistine eliminates patient misuse of nose drops, sprays and inhalants is not likely to produce rebound congestion nor make the patient "jittery "

Each Novahistine Tablet or teaspoonful of Elixir provides 5 0 mg of phenylephrine HCl and 12 5 mg of prophenpyridamine maleate For patients who need greater vasoconstriction, Novahistine *Fortis* Capsules contain twice the amount of phenylephrine
